1. SOUTHERN COUNTY.—PARTNERSHIP, with view to succession in two years, can be acquired in very old-established and increasing Practice situated in a beautiful residential and agricultural district within 10 miles of the sea. Cash receipts last year £3,154, including panel and appts. Visits 5/- to 21/-. Excellent rooms available until possession of Vendor's house is obtained. The half share will be sold. Premium 2 years' purchase. District developing and offers good scope.
2. PARTNERSHIP.—OXON.—Delightful residential district near good town.—A one-third share (to commence with) in an old-established good mixed-class Practice, averaging for the past three years £1,640, and offering good scope. Panel of nearly 1,000. Fees 3/6 to 21/-. Choice of two houses at rentals of £100 and £50 p.a. Sport of all kinds. Premium 2 years' purchase.
3. PARTNERSHIP.—SOUTH-WEST COAST.—Fashionable Watering-place. —Third or smaller share (producing about £1,200 p.a.) if wished, to commence with, is for disposal in an old-established non-dispensing Practice worth last year over £6,000, owing to the retirement, through ill health, of one of three partners. Ingoing partner must be competent to undertake surgical work. Good house, with garden, etc., available on rent or purchase. Premium for share 2 years' purchase.
4. SUSSEX COAST TOWN.—PARTNERSHIP.—A one-fifth share, to commence with, is offered in an old-established mixed-class Practice producing last year over £4,000 p.a., including panel of 2,200. Fees 3/- to 10/6. Good house, with 2 reception, 6 bedrooms, and professional rooms. Electric light. Garden. Garage. Rent on lease £100 p.a. Premium 2 years' purchase. Short preliminary assist'ship.
5. KENT.—LARGE TOWN.—Well-established middle and better-class non-panel PRACTICE, producing last year £5,000 p.a. Visits 5/- up. Suitable house, 3 reception, 4—5 bedrooms, etc. Rent on lease £63 p.a. Prem. £3,500, £2,000 down.
6. MIDLANDS.—COUNTY TOWN.—PARTNERSHIP.—A one-fourth share in an exceptionally sound non-dispensing mainly mixed and better-class Practice, averaging over £8,500 p.a. Small selected panel of 700. Fees 5/- to 21/-, average 7/-. Suitable house can be obtained. London, Oxford, or Cambridge Graduate preferred, age 30 to 35, and experienced in anæsthetics. Premium £4,000.
7. NEAR LEICESTER.—Old-established good middle-class Country PRACTICE, in attractive district. Average income £1,453, including panel of 1,250. Fees from 3/6. Mid. 3 gns. upwards. Good house in excellent repair, 3 reception, 6 bedrooms, etc., separate professional rooms. Garage. Garden of 3½ acres. Price freehold £2,800. £1,750 on mortgage, or might be rented. Premium £2,175.
8. SOUTH DEVON.—PARTNERSHIP.—Attractive Town close to sea.—A half share in a very old-established and rapidly increasing mixed general Practice. Average cash receipts for last 3 years £2,727, last year £3,521. Panel of 1,130. Fees 3/6 to 21/-. Good house in its own grounds with ample accommodation. Price freehold £1,900, £1,200 on mortgage. Premium £2,300. Cottage Hospital, and good scope for major surgery.
9. MADEIRA.—SEASONAL PRACTICE.—Receipts for immediate past 12 months £900. Fees 10/6 to 21/-, and a few at 7/6. Easily worked and good scope. Excellent climate. Premium £1,000.
10. BORDERS OF NORTHANTS AND LINCS.—Unopposed old-established Country PRACTICE, within easy reach of large town, and worth over £1,500 p.a., including panel (with mileage) £675, and appts. about £30. Visits 5/- to 20/-. Suitable house available. Rent £70 p.a., or can be bought. Premium 1½ years' purchase. Held by Vendor, who is retiring, over 30 years. Sport of all kinds.
11. WITHIN 100 MILES OF LONDON.—PARTNERSHIP.—A share producing about £1,200 p.a., with prospects, is for disposal owing to the retirement of one of the partners in an old-established Practice. Ingoing partner would reside in a pretty country district about 5 miles from pleasant country town, where main practice lies. No opposition. Total income about £8,000, including valuable appointments worth about £2,000, and panel. Very desirable residence (ample accommodation) with 2½ acres of ground available on lease at low rental of £60. Premium 2 years' purchase.
12. YORKS.—(North Riding).—Country PRACTICE in beautiful district. Average income over £750, including panel of about 330. Fees 3/6 to 21/-, medicine extra. Nearest opponent 4 miles. Suitable house with 2 reception, 4 bedrooms, etc., and garden of 1 acre. Rent on lease £30 p.a. Prem. 1½ years' purchase, part by instalments.
13. GLOS.—Favourite Town.—Mixed general non-dispensing PRACTICE. Income last year over £700, including panel of 550. Visits 3/6 to 10/6. Mid. 2 to 10 gns. Good house, in excellent position, with 3 reception, 3 bedrooms, etc. Rent on lease £75 p.a. Premium 1½ years' purchase. Suitable lady doctor.
14. LONDON, W.—Chiefly middle-class PRACTICE, averaging about £700 p.a., including panel of 750. Visits 3/6, 5/-. No midwifery. Suitable house, with 4 beds., etc. Rent on lease £96 p.a. Prem. £1,100.
15. MANCHESTER DISTRICT. — Old-established middle and working-class PRACTICE, worth last year about £700, including panel of 590, and capable of increase. Expenses small. Well-situated house, with 6 rooms in addition to professional rooms. Large garden. Price, freehold, £850. Moderate premium accepted.
16. CHANNEL ISLANDS.—Old-established better and middle-class PRACTICE, averaging about £1,000 p.a., but capable of increase. Fees 5/- to 21/-. Little midwifery. No panel. Large well-situated house with garden. Garage for 3 cars. Very pleasant social conditions. Premium for Practice and house £4,000, of which £1,500 to £2,000 could remain on mortgage.
17. KENT.—Old-established Country PRACTICE, in favourite locality, and within 5 miles of the coast. Income for past 12 months £1,185, and increasing. Visit 5/- to 21/-. Panel of about 380. Appts. worth about £50 p.a. Convenient house, with ample accommodation. Nice garden. Price for freehold £1,800. Premium 1½ years' purchase.
18. WITHIN TWENTY MILES OF LONDON.—Old-established good mixed-class PRACTICE, in attractive residential district. Receipts average £1,000 p.a. Panel of nearly 500 and appts. worth £60. Visits 3/6 to 21/-. Very nice house, with all modern conveniences and half acre of garden. Price for freehold £1,800. Premium £1,400.
19. DEATH VACANCY.—NORTH WALES.—Easily worked PRACTICE, offering large scope, in beautiful seaside and country district. Cash receipts for last twelve months about £1,200. Very convenient and commodious house can be rented on lease at £85 p.a. Premium £800. Very good Locum in charge.
20. ESSEX.—(Within 15 miles of London).—Old-established unopposed and increasing PRACTICE, in pretty country district. Income last year over £1,150, including Union £90 and panel £432. Comfortable house, with ample accommodation and large garden. Rent £70 p.a. on lease. Premium £1,650. Ill health reason for sale.
21. HOME COUNTIES.—Within few miles of large town.—Old-established unopposed and increasing PRACTICE, in pleasant district, worth over £3,000 p.a., including panel, with mileage, producing about £1,000 and appts. £260. Visits 3/6 to 10/6, medicine usually extra. Very little midwifery. Good house (7 bedrooms, etc.), garden, garage. Price, freehold, £2,000. Premium 1½ years' purchase.
22. CHESHIRE.—Industrial Town within easy reach of Manchester.—Well-established PRACTICE producing £2,600 p.a., with panel of 2,870. Fees 2/6 to 3/6, medicine extra. Good house, with ample accommodation. Price £1,000, or would be rented at £70 p.a. Premium 1½ years' purchase, half down and balance by instalments.
23. DEATH VACANCY.—SOUTH WALES.—Seaside Resort.—Old-established mixed-class PRACTICE in favourite locality. Receipts for past 12 months £1,400, including panel of 607. Visits 3/6 to 21/-. Convenient house, with 2 reception, 4-6 bedrooms, and professional rooms, etc. Rent on lease £80 p.a. Good sport and schools. Premium 1 year's purchase.
24. SOUTH AFRICA.—HEALTH RESORT (Inland Spa).—Old-established increasing PRACTICE (held over 20 years) on a main line of rail, and in a healthy pleasant township much frequented by visitors in the Season. Cash receipts average over £1,750 p.a., including several appts. One opponent. Price for house £1,250, to include furniture, instruments, and motor car (original cost £2,000), and for goodwill £1,250, part by instalments. Efficient introduction. A knowledge of Hydrology would be a big asset.
25. PARTNERSHIP.—STAFFORDSHIRE. — LARGE TOWN. — A one-third share is offered in a very sound old-established chiefly working-class Practice, averaging £3,700 p.a., including panel of nearly 5,000. Very suitable house, with 2 reception, 3 bedrooms, etc. Moderate rent. Premium only 1½ years' purchase, part by arrangement.
26. WORCS.—COUNTRY PRACTICE within easy reach of two good towns. Old-established, and averaging over £1,000 p.a., including panel of about 600. Fees 2/6 to 10/6. Good house, with ample accommodation. Rent on lease £85 p.a. Premium £1,350, £1,000 down, balance easy instalments.
27. SOMERSET.—Near Hospital Town, in very pleasant residential district, an old-established unopposed Country PRACTICE averaging over £900 p.a., including panel (producing about £400 p.a., with mileage and appts. Visits 3/6 to 21/-. Railway station in place. Nice house (5 bedrooms, dressing and bathroom, etc., garden). Price, freehold, £1,250, part on mortgage. Prem. £1,250, to include drugs, etc.
28. MANCHESTER.—Rapidly growing Suburb within 5 miles of the City.—Old-established mainly middle-class PRACTICE, producing a steady average income of £2,000. Panel of nearly 1,400. Fees 3/6 to 10/6. Large house and garden. Price, freehold, £2,500, or would be let on lease at £120 p.a. Premium £3,500.
29. SOUTH-WEST OF ENGLAND.—POPULAR COAST TOWN.—A one-third share in an old-established PRACTICE, having good surgical scope. Gross cash receipts average £4,200. Panel of 1,800. Suitable house available, on rental. Premium £2,250.
30. PARTNERSHIP.—SOUTH COAST.—Favourite Residential and Holiday Resort.—A one-third share, with increase later, in a well-established non-dispensing chiefly better-class Practice. Average income over £3,000 p.a., with large scope. Fees 5/- to 21/-. Very little midwifery. Good corner house, with 4 reception, 6 bedrooms, etc. Premium 2 years' purchase. Scope for surgery.
31. SOUTH-WEST OF ENGLAND.—GOOD HOSPITAL TOWN.—A one-half share in an old-established mixed-class PRACTICE is offered owing to the retirement of the Junior Partner. Gross cash receipts average £2,300 p.a., including good appts. Small panel. Low expenses. Commodious house, with garden and garage, rent £70 p.a. Premium 2 years' purchase. Vendor on staff of Hospital, and scope for surgery.

ASSISTANTS REQUIRED.—(1) North Wales.—Outdoor, married. Salary £450—£500 p.a., with unfurnished house. (2) Liverpool.—Outdoor; £300—£350, with furnished rooms, etc. (3) East London.—Indoor; £300 p.a. (4) Manchester.—Indoor, with view to Partnership. Preferably Scotch. (5) London.—Indoor. £250.

Full Schedule of Terms and Conditions will be forwarded on application.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

Throughout the span

of allotted years — from infancy with restricted diet, through manhood with irregularity of habits, to old age with failing muscular strength and intestinal atony, constipation besets "all types and conditions of men."

The remedy lies not in the doubtful results of harsh cathartics, but in helping the colon back to normal activity.

AGAROL
BRAND COMPOUND

The original agar-agar emulsion

is dependable, mild, non-irritating to the organs. It lubricates the intestinal tract, softens the impacted fæces, and reactivates the peristaltic force and action.

A liberal quantity of Agarol Brand Compound for trial sent without cost or obligation to physicians.

Agarol Brand Compound is the original Mineral Oil—Agar-Agar Emulsion with Phenolphthalein and has these advantages:
Perfect emulsification; stability; pleasant taste without artificial flavouring; free from sugar, alkalies and alcohol; no oil leakage; no griping or pain; no nausea; not habit forming.

AMENORRHEA DYSMENORRHEA

"It is a very great mistake to treat amenorrhea as though it were simply a lack of the catamenia, for it is a great deal more than that. Behind this lack lies a cause. It may be in the uterus or the ovaries, or it may be still farther back in the secretions of the endocrine glands or in the functioning of the vegetative nervous system."—("The Treatment of Amenorrhea," Dalché, *Revue Française de Gynecologie et d'Obstetrique*, May 1, 1920.)

In the treatment of irregularities of the catamenia, rational therapeutic procedure is directed to the restoration of normal balance in the endocrine and vegetative nervous systems.

Hormotone
BRAND

contains thyroid, pituitary, adrenal, and gonad substance, combined to take advantage of the demonstrated synergism existing between them. In the treatment of these disorders Hormotone has been very successful.

Dose: One or two tablets three times daily.

Adrephine

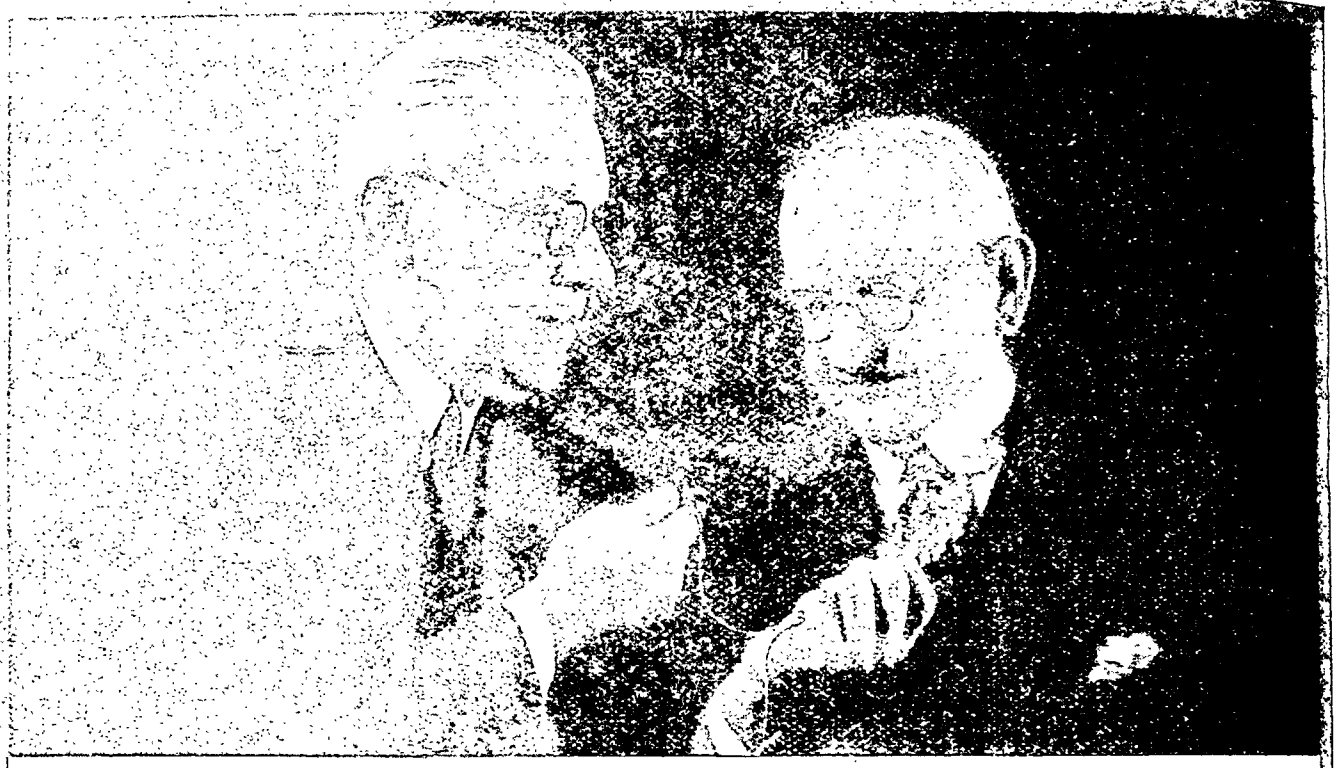
A Combination of Adrenalin and Ephedrine

ADREPHINE is an Adrenalin-Ephedrine compound in aqueous solution, containing Adrenalin 1:10,000, Ephedrine sulphate 2%, with 0·5% of chloretone as a preservative.

Adrenalin was introduced to the medical profession by Parke, Davis & Co. nearly thirty years ago, and has probably been put to more uses than any other single member of the whole materia medica. Its dramatic effects as a cardiac stimulant, in the treatment of asthma, and in controlling hæmorrhage, are well known.

Ephedrine, an alkaloid obtained from the Chinese plant, Ma Huang (*Ephedra sinica*) (a drug actually in medical use in the Far East for a thousand years), is of recent introduction to the Western world. It has been shown to possess properties similar to Adrenalin, but it is slower in action, and a combination of the two medicaments should be of decided value for topical application to mucous membranes.

Adrephine is such a combination. It ensures the prompt, vigorous action of Adrenalin, supplemented by the more sustained effect of the Ephedrine. It is suggested for use by topical application to the mucous membranes of the nose, throat or larynx, especially when it is desired to shrink the accessible mucous membranes of the respiratory tract. It has also been used in the treatment of asthma (from vegetable or animal emanations, or other sources), epistaxis, etc., in all of which it has proved of great value.



Supplied in vials of 10 c.c. and bottles of 1 ounce.

THE CURTIS ABDOMINAL SUPPORT

(MODEL No 1)

FOR EFFICIENCY

Based on the principle of a direct anterior-posterior pressure, the Curtis Abdominal Support enjoys considerable advantage over any other support on the market.

It gives direct abdominal uplift without any cramping or binding of the hips whatsoever, which is maintained in any position that the patient may assume. May be adjusted to any degree the physician may prescribe, and is simply fastened by a strap and buckle.

For full particulars apply to:

LEWIS'S PUBLICATIONS

JUST PUBLISHED. SECOND EDITION. With 74 Illustrations on 31 Plates and in the Text. Demy 8vo. 16s. net; postage 9d.

A SHORTER SURGERY

A Practical Manual for Senior Students

By R. J. McNEILL LOVE, M.B., M.S.Lond., F.R.C.S.Eng.,
Assistant Surgeon, Metropolitan Hospital; Hunterian Professor, Royal College of Surgeons, etc.

Extract from Review of First Edition:—". . . embodies in a clear and concise manner the more important principles. The book is written from a practical point of view. . . . Mr. Love is to be congratulated."—*British Medical Journal.*

JUST PUBLISHED. With 7 Coloured Plates and 33 other Illustrations. Demy 8vo. 10s. 6d. net; postage 6d.

AFFECTIONS OF THE EYE IN GENERAL PRACTICE

By R. LINDSAY REA, M.D., F.R.C.S.,
Ophthalmic Surgeon to the West End Hospital for Nervous Diseases; Surgeon to the Western Ophthalmic Hosp., etc.

THIRTEENTH EDITION. With 9 Coloured Plates and 272 other Illustrations. Demy 8vo. 21s. net; postage 9d.

SWANZY'S HANDBOOK OF DISEASES OF THE EYE AND THEIR TREATMENT

Revised and Edited by LOUIS WERNER, M.B., F.R.C.S.I., Surgeon, Royal Victoria Eye and Ear Hospital; Professor of Ophthalmology, University College, Dublin; and Examiner in Ophthalmology, Dublin University.

"Swanzy's textbook . . . undoubtedly remains one of the best. One of the features of this volume is the excellence of the illustrations."
—*The Lancet.*

FIFTH EDITION. Revised and Enlarged. With 11 Plates (6 Coloured) and 76 other Illustrations. Demy 8vo. 21s. net; postage 9d.

MIND AND ITS DISORDERS

A Textbook for Students and Practitioners.

By W. H. B. STODDART, M.D. Lond., F.R.C.P., Physician for Mental Diseases, St. Thomas's Hospital; late Examiner in Psychology and Mental Diseases to the University of London, etc.

". . . . ranks high among standard English works. It is written in a clear, concise style."—*The Lancet.*

SEVENTH EDITION. With New Illustrations (mostly in Colour). Demy 8vo. 7s. 6d. net; postage 5d.

LANDMARKS AND SURFACE-MARKINGS OF THE HUMAN BODY

By L. BATHE RAWLING, M.B., B.C.Cantab., F.R.C.S.Eng., Surgeon to St. Bartholomew's Hospital, etc.

"This edition will doubtless be as popular as its predecessors, both with students and surgeons."—*British Medical Journal.*

With 186 Illustrations, included in 93 Plates (1 Coloured) and the Text. Demy 8vo. 25s. net; postage 9d.

CHRONIC (Non-Tuberculous) ARTHRITIS

Pathology and Principles of Modern Treatment.

By A. G. TIMBRELL FISHER, M.C., F.R.C.S.Eng., late Hunterian Professor, Royal College of Surgeons of England; Assistant, Surgical Unit, University College Hospital, etc.

"Mr. Timbrell Fisher has established the existence of facts hitherto unknown and has made valuable contributions to our knowledge. His book is to be recommended."—*British Medical Journal.*

BY THE SAME AUTHOR.

With 79 Illustrations on 40 Plates and 1 Text figure. Demy 8vo. 12s. 6d. net; postage 6d.

INTERNAL DERANGEMENTS of the KNEE-JOINT:

Their Pathology and Treatment by Modern Methods.

"An admirable monograph which may be regarded as a type of what a monograph should be."—*The Practitioner.*

BY THE SAME AUTHOR.

With 62 Illustrations. Demy 8vo. 9s. net; postage 5d.

TREATMENT BY MANIPULATION

A Practical Handbook for the Practitioner and Student.

"This edition will no doubt be even more welcome to the profession than its predecessor."—*The Lancet.*

". . . one is carried away by the admirable presentation of the subject . . . forcible, clear, and concise . . . deserves to be well studied by physician and surgeon alike."—*Journal of Bone and Joint Surgery.*

EIGHTH EDITION. With 2 Plates and 91 other Illustrations. Demy 8vo. 21s. net; postage 9d.

HYGIENE AND PUBLIC HEALTH

(PARKES AND KENWOOD).

Revised by HENRY R. KENWOOD, C.M.G., M.B., F.R.S.Edin., D.P.H.Lond., Emeritus Professor of Hygiene and Public Health in the University of London, etc.; and HAROLD KERR, O.B.E., M.A.Dunelm, M.D.Edin., D.P.H.Camb., Professor of Hygiene and Public Health in the University of Durham, etc.

"Here we have a quarry of concise information valuable to students and practical workers, a bargain at the price asked for it."
—*British Medical Journal.*

With 50 Illustrations. Crown 8vo. 5s. net; postage 3d.

BRANCHIAL CYSTS

and other Essays on Surgical Subjects in the Facio-Cervical Region.

By HAMILTON BAILEY, F.R.C.S.Eng., Surgeon, Dudley Road Hospital, Birmingham; late Assistant Surgeon, Surgical Registrar and Tutor, Liverpool Royal Infirmary, etc.

"Of definite practical value . . . the present volume is decidedly opportune."—*British Journal of Surgery.*

With 25 Illustrations, including 17 Plates. 9s. net; postage 5d.

STERILITY IN WOMEN: Diagnosis and Treatment

By SIDNEY FORSDIKE, M.D., B.S.Lond., F.R.C.S.Eng. and Ed., Surgeon to the Hospital for Women, Soho Square, London; Gynæcological Surgeon to the Kensington, Fulham and Chelsea Hospital; Author of "The Effects of Radium upon Living Tissues," etc.

"The monograph shows in every page evidence of rich personal experience, and will well repay the most careful study."—*The Lancet.*

HEART DISEASE IN CHILDHOOD

BY

H. B. RUSSELL, M.D., M.R.C.P.(Lond.),

Medical Officer in charge of the Electrocardiographic Department, St. Thomas's Hospital; Assistant Physician, Queen's Hospital for Children, Hackney;

AND

C. K. J. HAMILTON, B.M.(Oxon.), M.R.C.P.(Lond.),

Physician in charge of the Children's Department, Charing Cross Hospital; late Johnson and Temple Research Fellow in Diseases of Children, St. Thomas's Hospital.

Demy 8vo. vii + 103 pages. 7s. 6d. net.

HEART DISEASE IN CHILDHOOD covers a very extensive field, and in order to keep this volume within reasonable bounds the authors have limited themselves to a discussion of the essentials only of the disease.

It is generally recognised that rheumatism is the cause of most cases of heart trouble in children and a chapter has, therefore, been devoted entirely to the consideration of this disease.

The symptoms of and treatment for Acute Rheumatic Pericarditis, Endocarditis, Myocarditis, and Congenital Heart Disease are all dealt with in the same lucid way that will commend itself to the practitioner and student and all those who have children under their care.

Of considerable interest also is a full chapter on the Electrocardiograph and its application and uses.

SOME APPRECIATIONS:

"The book can be recommended as a brief, reliable, and scientific account of the subject it deals with."—*The Edinburgh Medical Journal.*

"This is a concise and clearly written book, useful to the practitioner and all those who have children under their care."—*Journal of State Medicine.*

"The authors have treated their subject in a lucid and most able manner, discussing the problems with which every practitioner has to contend, and explaining methods of diagnosis and treatment."—*Medical Times.*

"It is a compact volume containing much useful information."—*British Medical Journal.*

BRITISH TRIUMPH IN MONTE CARLO RALLY

THE HON. MRS. BRUCE ARRIVES ON TIME

In covering 2,150 miles in 91 hours from Lapland to the sunny Riviera, the Hillman "Straight Eight" and its driver, the Hon. Mrs. Victor Bruce, have accomplished one of the most difficult performances in the history of motoring. In spite of the most terrible conditions, the Hon. Mrs. Bruce was the first woman motorist and also first in the British contingent to arrive. Once more the supreme reliability of the Hillman "Straight Eight" has been proved to the hilt.

Write for Catalogue H/59 and copy of Mrs. Bruce's book, "From Arctic to Mediterranean in 91 hours."

Hillman "Straight Eight" Saloon £445.
Other "Straight Eights" from £430.
"Fourteens" from £310.

ULTRA-VIOLET LIGHT

THE types illustrated are but two of our many models which provide at economical cost a highly efficient source of Ultra-Violet Radiation. Widely approved by the Medical Profession on account of their simplicity and dependability, and 100% British.

WARNING

We would urge that intending purchasers of any ultra-violet light apparatus (small or large) should insist on examining by a spectroscope the apparatus concerned. Full facilities for this are given at our showrooms.

THE DR. PERCY HALL U.V. APPARATUS

(Dual Purpose Model)

Provides in a single apparatus the means of applying Ultra-Violet Radiation either generally, locally, or internally by quartz applicators or specula. Acknowledged to be the most perfect type yet designed.

Price, for use on direct current - £38
Price, „ alternating „ - £53

THE "MEDISUN U.V." APPARATUS

Quartz Mercury Vapour Type.

Designed for whole body or local applications.
Suitable for general practitioners, or for use in the homes of private patients.

Price, for use on direct current - £12
Price, „ alternating „ - £18
Telescopic Stand, as illustrated, £3 extra

Famous as **The Food of Royal Infants**

also for invalids, the aged, and all persons of weak digestion

ROBB'S NURSERY BISCUITS have no equal. Easy of assimilation, a nourishing and sustaining diet, its appetising flavour is greatly appreciated by both young and old. Very welcome as a substitute for the ordinary bread-and-milk diet. Can also be lightly baked, with eggs and milk, to supply a delicious custard pudding.

Robb's NURSERY BISCUITS

Highly recommended by eminent Accoucheurs and Physicians, throughout the world as the most reliable food for Infants over six or seven months.

ROBB'S NURSERY BISCUIT POWDER is recommended when a feeding bottle is to be used, also as a diet for invalids, Nursing mothers and the aged.

ROBB'S DIGESTIVE RUSKS, TOPS and BOTTOMS, GINGER NUTS, and CHARCOAL BISCUITS are specially recommended for invalids and convalescents.

Send for large free sample and descriptive booklet, etc.

Alex. Robb & Co Ltd (Dept. 6), NURSERY BISCUIT FACTORY, ATKINS ROAD, CLAPHAM PARK, LONDON, S.W.12.

Also in exactly similar form and price—
SOLID IODINE

A Remarkable advance in the presentation of H_2O_2

Owing to the rapidity in which H_2O_2 ordinarily loses its strength, it has not usually been practicable to carry a supply about without risk of frequent replacement; also, of course, of breakage.
Now a new process has been introduced of presenting Peroxide of Hydrogen in a solidified form, so as to enable it to be included conveniently in the physician's or surgeon's everyday case of instruments, etc.

This Solidified Peroxide of Hydrogen is known under the trade name of 'Peroxtik.' It is guaranteed to maintain its original 10-volume strength for a reasonable period.
A full-size tube of this new product will gladly be sent to the Medical Profession FREE on application to the Medical Dept., Messrs. ARTHUR H. COX & CO., LTD., 95, Lewes Road, Brighton, or can be purchased from the usual sources, at the cost of 1/3.

'Peroxtik'
SOLIDIFIED PEROXIDE OF HYDROGEN
in neat, handy glass tubes.

"HOMMEL'S HAEMATOGEN"

A natural organic TONIC associated with nourishing albuminous proteids.

AN EFFICACIOUS REMEDY IN ALL FORMS OF ANÆMIA, associated with constitutional diseases.

Obtainable in **Syrup** *and* **Tablets.**

"SEDIN"

Nervinum-Sedativum

Consisting of

Pot. Brom.	0.4 gramme	(grains 6½	approx.)
Sod. ,,	0.4 ,,	(grains 6½	approx.)
Ammon. ,,	0.2 ,,	(grains 3	approx.)
Salt	0.1 ,,		

combined with Vegetable Extract in form of soup tablets. (A disguised dietetic form.)

Samples free and carriage paid on application to—

NOVOCAIN

The Original Preparation
English Trade Mark No. 276477 (1905).

Local Anæsthesia in Surgical Practice

CLEFT PALATE.

TYPICAL CASE.

E. M., aged 25 years.

Diagnosis: Cleft palate.

Operation: Plastic repair.

Anæsthesia: Novocain-Adrenaline solution.

Operation: Nerves were blocked with a 2 per cent. Novocain-Adrenaline solution, 30 c.c. in all being used. In addition to the nerve block, an effort was made to separate the soft tissues from the bone by the "blowing-off" process. This was signally successful, the subsequent raising of the mucoperiosteum being greatly facilitated by this preliminary manœuvre. The palate united completely with the exception of an opening the size of a lead-pencil at the mid-point. This opening was later closed after making a local infiltration with Novocain-Adrenaline solution.

—EXTRACT from PRACTICAL LOCAL ANÆSTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anæsthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANÆSTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

If your patient must stop sugar

It is well known to the Medical Profession that a child's craving for sweets is natural, as a child requires a large supply of an easily assimilated hydrocarbon. Unfortunately ordinary sugar upsets the digestive functions of some children, and "glucose," recommended in its place, is too often of unknown composition and too expensive.

The monosaccharides of fruit-sugar offer obvious advantages over the di-saccharide, sucrose, and a pure and very palatable mixture of dextrose and lævulose is now available under the trade name of SUNNYCOMB.

SUNNYCOMB was first made at the request of some members of the Medical Profession who desired a reasonably cheap monosaccharide for sweetening baby-food for babies who were not flourishing. The results were so satisfactory, and the product so palatable to both young and old, that it was decided to make it generally available.

SUNNYCOMB supplies the necessary carbohydrates in an easily digestible form, being so readily assimilated that it does not upset the digestive functions as ordinary sugar sometimes does, yet it is at the same time a pleasing and appetising delicacy.

SUNNYCOMB is made by Macfie & Sons, Limited, who first started in 1788 and have been sugar refiners in Liverpool continuously since 1837. They guarantee it to be a pure wholesome product and will willingly supply free samples and full information about it to any member of the Medical Profession on receipt of a postcard.

DIMOL PESSARIES

For Reliable Antisepsis in Midwifery and Gynaecology

The Dimol Laboratories have the pleasure of introducing to the notice of the Profession this new adaptation of their potent, non-toxic benzene derivative.

In view of the high guaranteed bactericidal efficiency of these pessaries it is self-evident that their slow non-toxic action must be of great value in keeping the uterine and vaginal passages free from infections.

Each Dimol Pessary is guaranteed equal in *bactericidal action* to ½ drachm pure carbolic acid, to be free from any deleterious action on the mucosa, and to be non-toxic to the blood and lymphatic systems.

Price in cartons of Twelve—4/6 Professional Discount 20%

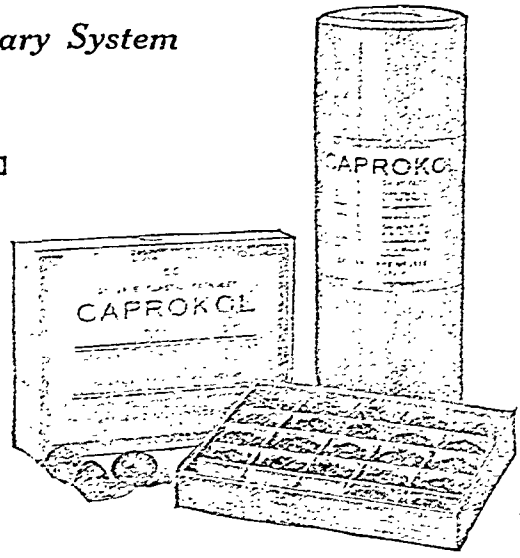
In the Treatment of



Disorders of the Urinary System

CAPROKOL

produces a comforting analgesic effect and simultaneously exerts a powerful antiseptic action.

Caprokol therapy relieves the patient with surprising rapidity. Pain and fever abate immediately, as the urinary mucosa is soothed; frequency of micturition diminishes, normal appetite returns, and regular restful sleep is rendered possible.

Persistent treatment results, in the majority of cases, in sterilisation of the urinary tract with complete restoration to health.

'Allenburys' Diabetic Flour

Is a special preparation of caseins and lactalbumen to which leavening agents are added.

It is a satisfactory and convenient product for the preparation of special foods, free from carbohydrates, and containing a minimum of fat; or definite proportions of these may be added as tolerance increases with the progress of the treatment. The 'Allenburys' Diabetic Flour is compact, convenient to use, and keeps well. From it may be prepared a variety of palatable and highly nutritious foods of special composition. Recipes and directions for use are enclosed with each packet.

PERCENTAGE COMPOSITION:
Special Casein 87·0 Fat 0·7 Sodium Bicarbonate 1·6
Acid Potassium Tartrate 1·6 Moisture 9·1
Calorific Value—303 calories per 100 grammes or 1,376 calories per lb.

Further particulars and clinical trial sample will be sent on request.

LIVER EXTRACT B.D.H.

Results obtained in a series of 80 cases of pernicious anæmia reported upon recently (*B.M.J.*, Dec. 14, 1929) confirm the fact that liver therapy is remarkably beneficial in this distressing disease.

Current experimental work indicates that liver treatment is to become a routine measure also in secondary anæmias, such as those associated with pregnancy and with post-partum hæmorrhage.

Literature on request

The clinical value of Liver Extract B.D.H. in all the conditions mentioned above is now well established. Liver Extract B.D.H. is made under rigid supervision in the B.D.H. laboratories by a special process tested and found efficient by the Medical Research Council.

In it all the therapeutic activity of fresh liver is maintained, the resulting product being highly potent and at the same time so palatable that it is regarded by the patient as a savoury rather than as a medicine.

HOW GIBBS HELPS THE DOCTOR

The Scope of Gibbs Educational Work

The educational work carried on by Gibbs is of tremendous value to the Doctor. By means of this highly organised effort a very large section of the public is reached during the most impressionable age—childhood. They are taught a great deal about their teeth—their construction and how Nature builds them—how they are finally formed—and the best way to preserve them in all their natural beauty.

Not only is this of great value in impressing upon the children the vital need that great care should be taken of the teeth, but this educational background is a useful field in which the Doctor may plant his special advice or instructions. More intelligent heed is given his words. Gibbs educational programme includes:—

IVORY CASTLE LEAGUE AND CRUSADE

The primary object of the League is to put into the hands of all who are interested in the promotion of Oral Hygiene the means of interesting the rising generation in their own welfare.

Membership of the League is open to all bona fide Teachers and accredited persons interested in the state of Children's teeth. Crusaders are enrolled by their teacher.

BOOKS AND CHARTS

For the Juniors, Fairy Books are provided. For Seniors, the booklet, "My teeth and how to defend them."

A set of eight Charts has been prepared illustrating the Formation, Structure and Care of the Teeth.

TOOTH BRUSH SCHEME, FILM AND SLIDES

To establish the Tooth Brush Habit the House of Gibbs will supply at nominal cost, SETS consisting of one Tooth Brush and tin of Dentifrice.

Four sets of slides with a lecture on Dental Hygiene, and/or a fascinating fairy film free on loan.

GIBBS DENTURE TABLET

Gibbs new Denture Tablet is for cleaning Dental Plates, Bridgework (both gold and vulcanite) and artificial teeth. It gives a high polish, removes stains, makes plate or teeth sterile and antiseptic without in anyway injuring the softest gold or the finest vulcanite or platinum. The formula has been submitted to and approved by important members of the Medical Profession.

Gibbs Dentifrice

Literature, propaganda material, kinematograph films, leaflets, etc., as well as samples, are always freely at your disposal. Address: Dental Dept. D. & W. Gibbs Ltd., London, E.1.

GD/Dr/2a

Action of Lysolat compared with that of Carbolic Acid on Pathogenic Organisms

The exceptional germicidal value of Lysolat is due, in great part, to its solubility and stability even in circumstances that destroy other antiseptics. The left-hand test tube below shows Lysolat in a state of perfect emulsification in a 3% solution of Sodium Chloride, whilst a well-known liquid Lysol (right-hand test tube) has broken down under the same conditions.

A number of significant experiments have been made by Prof. Edmund Huynen of the State Veterinary University of Brussels to test the efficacy of Lysolat as a germicide. He used 1% solutions of Lysolat and of Carbolic Acid. It was ascertained that while the Lysolat solution represented a cresol concentration 3.5 times weaker than the carbolic acid solution, it was actually 5 times more powerful.

The following are the results of Prof. Huynen's experiments:

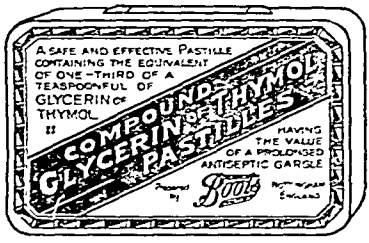
(1) Bacilli Pyocyaneus and Coli were destroyed by the Lysolat solution in 8 mins. at 18°, in 5 mins. at 26°, and in 2 mins. at 37°.

(2) Bacilli Bang and Paratyphoid were destroyed by the Lysolat solution in 1 min. at 37°.

(3) Bacillus Staphylococcus was destroyed by the Lysolat solution in 4 mins. at 37°.

In the latter case the carbolic acid solution required a contact of 120 mins. to destroy the Staphylococcus under identical conditions. At 26° the Lysolat solution proved to be 15 times stronger, and at 18° 12 times stronger than the solution of carbolic acid.

Lysolats



PATENT 118667 (LYSOL TABLETS)

Lysolats are packed in handy tins containing 40 and 80 tablets (at 1/3 and 2/- respectively), and also in tins of 1,000 tablets.

Members of the Medical Profession are invited to write for free samples of Lysolats to Solidol Chemical Ltd., Ashmead House, Disney St., London, S.E.1

COMPOUND GLYCERIN OF THYMOL PASTILLES

Full size trial tin free to Medical Practitioners in the British Isles on application to Boots The Chemists, Station Street, Nottingham.

The increasing use of Compound Glycerin of Thymol as an antiseptic and anti-catarrhal wash has suggested to us the introduction of this Pastille. Each Pastille contains the equivalent of 20 minims of Glycerinum Thymol Co. B.P.C., fortified by the addition of a powerful new antiseptic, Amyl-Meta-Cresol, discovered in the Research Laboratories of Boots Pure Drug Co. Ltd.

This antiseptic has a R.W. co-efficient of 250, and the equivalent of 2½ grains of pure Phenol has been added to each pastille.

The Pastilles have a refreshing flavour and will be found entirely pleasant in use.

OBTAINABLE FROM ALL BRANCHES OF

Boots Pure Drug Co., Ltd., Nottingham.

Intestinal Debility

"Cristolax" is worthy of careful trial in all cases of constipation. It is composed of 50 per cent. of the purest medicinal paraffin in combination with 50 per cent. of "Wander" Dry Malt Extract. The paraffin content acts mechanically for expelling the fæces, while the high diastatic property of the malt extract assists digestion and improves nutrition.

Where the patient has been accustomed to use an ordinary laxative regularly it is recommended that this should be continued in diminishing doses with the "Cristolax" treatment. It is quickly found that the "Cristolax" method of intestinal lubrication will alone ensure adequate and regular defecation.

Patients highly approve the pleasant flavour of "Cristolax," the complete absence of oiliness and its cleanly form.

M129

Irritable Bowel

Nujol is of great assistance in the treatment of chronic irritable bowel. Unlike cathartics, whose action is stimulating to the muscles or irritating to the lining of the intestines causing excessive secretion of mucus, Nujol acts merely as a gentle lubricant and solvent of impacted fecal matter. Though it absorbs intestinal toxins to a high degree, it cannot, itself, be absorbed. Consequently, toxemia is prevented, peristalsis is at a natural rate, and the stool is normal and properly formed.

R AND D

Specially indicated in

NEPHRITIS - URÆMIA - ECLAMPSIA - ALBUMINURIA

and allied conditions.

PROMPT and proper diagnosis of kidney conditions is necessary in cases of Bright's disease and all types of renal disorders. In nine cases out of ten the administration of a specific capable of producing real results in compensating for the loss of kidney function is also necessary.

For more than a quarter of a century Nephritin has been a sheet anchor to physicians in treating such disorders. Nephritin Tablets induce a marked increase in nitrogenous waste elimination. They reactivate the cells of the kidney, increase urinary secretion, and induce a greater output of urea.

Given in sufficient dosage these tablets produce marked results, and restoration to normal is quickly stimulated. They are invaluable also as a prophylactic in renal complications of infectious diseases and during pregnancy. The tablets are composed of the hormones of the normal kidney as they appear in nature—*absolutely unaltered.*

Samples and Descriptive Literature from Sole Distributing Agents for U.K. and Irish Free State: COATES & COOPER, 41, Great Tower Street, London, E.C.3.

NEARLY A CENTURY OF ACHIEVEMENT LIES BEHIND THEIR MAKING

THE exclusive process known only to Brand & Company of extracting their essences was first evolved nearly a century ago by Mr. Brand in collaboration with a celebrated physician.

The valuable restorative and stimulating properties of these essences were immediately recognized by the Medical profession which has prescribed them ever since.

When appetites are failing and patients are reluctant to eat, Brand's Essences promote appetite. For by stimulating the gastric juices they prepare the patient for more solid diet.

By a special process Brand's Essences are made entirely of the pure juices from freshly killed meats.

Brand's Essences (Beef, Mutton and Chicken) can be obtained throughout the world at chemists and stores in small and large-sized tins and jars. Brand & Co. Ltd., Mayfair Works, South Lambeth Road, London, S.W.8.

OVARNON in DYSMENORRHŒA

_____ *London,*
Jan. 14, 1930.

" *Dear Sir,*

In answer to your enquiry of the 30th ult., I have been able to try Ovarnon in the case of Dysmenorrhœa in a girl of 20. She has been so ill each month during her menstrual period that she has been confined to bed for the greater part of four days. She has taken one Ovarnon tablet each day since her last menstrual period, with the consequence that she has just finished the first painless menstrual period she has ever experienced.

Believe me,
Yours faithfully,
_____ *M.R.C.S.*"

Each dragée contains 5 mouse units of the STANDARDISED ovarian hormone (Menformon) and 150 mg. of desiccated ovarian powder.
In boxes of 50.

Manufactured by The ORGANON LABORATORIES, OSS (Holland).

(*Aesculapius*)

ANÆMIAS

The healthy state implies a balance between blood destruction and blood formation. The duty of the blood is to maintain proper nutrition and restoration of the tissues, to preserve itself in the face of hæmorrhage by clotting, and to act as a common carrier for immune substances, hormones and vitamines; the normal function of both blood-forming and blood-destroying organs is to maintain the elements of the blood in normal characteristics and numbers; the blood count at any given time is necessarily a numerical expression of the balance of this, what might be termed, profit and loss system. In the anæmias this balance is upset, and alarming decreases in the actual number of cells present occur. This may be brought about by any one of the following factors:—

(*a*) There may be greatly decreased production.
(*b*) There may be greatly increased destruction.
(*c*) There may be a combination of decreased production with increased destruction.

The evidences we get of abnormal blood destruction are primarily oligocythæmia, or diminution in the number of cells, the appearance of small microcytes, fragmented red cells, the phagocytosis of corpuscles by the clasmatocytes, the deposits of iron pigment, and the abnormal features of bile pigment metabolism. Indications of abnormal blood formation may be found in the appearance of macrocytes and microcytes in the circulation as well as occasionally the occurrence of nucleated red blood cells, especially of the group known as megaloblasts. Evidences of blood regeneration consist in the appearance of immature red blood cells, which include nucleated forms, reticulocytes, etc., together with an increased red cell count, and increased hæmoglobin percentage.

HEPATEX

Prepared by a standardised process from carefully selected livers, Hepatex is so concentrated that each dose of one fluid drachm contains the essential therapeutic principles of two ounces of fresh liver. It is recognised to be the most convenient form of Liver Extract for the treatment of Pernicious Anæmia.

Issued in 4-oz. bottles @ 12/- each.

HEPATEX WITH IRON

In this combination the special form of iron used is superior to the ordinary iron preparations, being easily assimilable and producing no disagreeable after-effects. One fluid drachm contains one grain of iron and the equivalent of two ounces of liver. It is strongly recommended for cases of stubborn secondary anæmia where powerful stimulation of the blood-regenerating organs is desirable.

Issued in 2-oz. bottles @ 7/6 each.

HÆMEX

An improved adaptation of classical remedies in which the tonic and blood-forming properties of hæmoglobin and iron are presented in palatable form. Each dessertspoonful dose contains 1½ grains metallic iron. Patients suffering from a secondary anæmia due to any chronic infection will benefit from its use. It is also indicated in anæmia following any of the acute fevers, particularly after influenza.

Issued in 8-oz. bottles @ 3/- and 16-oz. bottles @ 5/6.

Milk Intolerance.

For many years Benger's Food, as is well known, has been used by practitioners throughout the world as a routine diet in all gastric cases, debility, and in cases of milk intolerance. The reason for this may be briefly stated:—

Benger's Food is a special wheaten flour preparation containing, in suitable amount, the two natural digestive principles — Amylopsin and Trypsin — in a latent state.

It is devised and expressly intended to be used in conjunction with fresh cows' milk, or diluted milk, if desired.

The two enzymes are in such condition as to exert their digestive powers under the condition which obtains during the preparation for use.

The Amylopsin acts on the carbohydrates (Starch) of the Food and gradually changes it into soluble sugars (Dextrins and Maltose mainly, with a little Dextrose) more or less according to the length of time allowed for digestion.

The Trypsin acts on the gluten of the flour and on the proteins (Casein, etc.) of the milk so that the curd which forms is softened, and as a result it separates in the stomach in fine readily-digestible flocculi instead of large, often indigestible curds. The extent of digestion can be varied; *it is important to note that complete pre-digestion can never take place.*

Benger's Food contains no preservatives. It is palatable and is free from rough irritant particles.

These considerations show that Benger's Food is not merely a mechanical milk modifier — it is a real modifier of a peculiar character.

THE "LANCET"
describes it as "Mr. Benger's admirable preparation."

A Physician's sample will be sent post free to any member of the Medical Profession making application to the Proprietors:—

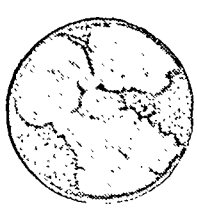
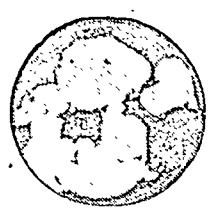
NATURALLY RICH  IN VITAMIN "D"

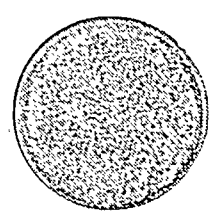
Smiler, fed on Cow & Gate



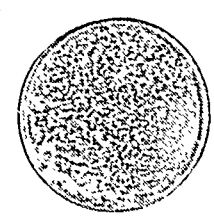
DIGESTIBILITY



In contradistinction to the heavy, large, and indigestible curds which are given by the action of rennin on Cow's milk and milks dried by the spray process, reconstituted Cow and Gate Milk gives a light flocculent precipitate, very similar to that of Breast Milk. A recent investigation has shown that the same results are obtained by using enzymes from human sources and that the improved Cow and Gate Roller Process does not alter the proteins to an extent which interferes with their subsequent easy digestion.



The use of such alkaline agents as Sodium Citrate and Lime, to prevent this leathery curd formation, is therefore entirely superseded. In fact, it has been shown (Hess: Feeding and Nutritional Disorders in Infancy) that these agents, while retarding the formation of hard curds, also inhibit, most decidedly, peptic digestion owing to their increased buffer action, and in addition they have a destructive effect on Vitamin C.



This denaturisation of the proteins in Cow and Gate is brought about by an improved Roller Process, which also preserves intact the Vitamin and mineral content of the original rich milk of Somerset and Dorset.

Vita-Weat—the perfect "staff of life"

Analysis and tests of Vita-Weat, the British whole-wheat crispbread, show that it possesses in a marked degree the six essential constituents—carbohydrates, fat, proteins, mineral salts, water, *and the essential vitamins.*

100% Whole Wheat.

Being made from the whole wheat berry, from which nothing has been removed in manufacture, Vita-Weat yields the highest natural percentage of cereal proteins, and by the process of manufacture the starch present is rendered easily available for the solvent action of the amylolytic ferments of the human digestive juices.

Further, Vita-Weat is specially valuable as a natural stimulant to peristaltic action of the intestines, and when forming a suitable proportion of the daily diet effectively counteracts constipation.

Vitamins A, D, and B.

The dry condition of Vita-Weat is of distinct advantage in cases of flatulence in which moist foods are largely contra-indicated, and the crisp character of the sections also helps to reduce the intake of soft foods, giving the teeth and masticating muscles something to do and ensuring complete and thorough salivation of the food bolus.

Vita-Weat crispbread presents the whole wheat berry in a concentrated, attractive and digestible form with the Vitamins A, D & B in an active condition, and it forms a valuable addition to rational diet, presenting a dainty and advantageous alternative to soft wholemeal or white bread.

Wulfing Products

The Pale and Weakly Child

Particularly the type in which a definite pathology cannot be demonstrated, generally responds well to calcium therapy in the form of Kalzana. For instance, a recent clinical report states:

> *"I gave Kalzana to a child with peculiar symptoms of apathy, listlessness, etc. There has been a marked improvement—she sleeps better, and takes her food with some appetite."*

The clinical results produced by Kalzana are equally satisfactory in diseases of children amenable to calcium medication, especially in tubercular disease, and the type of malnutrition associated with acute infectious disorders.

Kalzana is a definite chemical combination of calcium-lactate and sodium-lactate in the form of a double salt. The special virtue of the product is due to the action of the sodium in raising the blood alkalinity to the extent necessary to secure the adequate retention of the calcium constituent. Therefore Kalzana therapy means calcium retention. It is used in over 200 British Hospitals and Sanatoria, including many leading Children's Hospitals.

Dispensed by Chemists in air-tight packets containing 50 and 100 tablets.

Kalzana

THE LIME FOOD

Precision in Infant Feeding

Every requirement needed to provide a correctly balanced infant's food is supplied by properly modified cow's milk and Albulactin. The all-important proteid and lactalbumin percentages are exactly correct, and *always* within the control of the physician; an important consideration when the food has to be adapted to the peculiar digestive capacities of individual infants.

Albulactin is pure lactalbumin—the vital proteid of human milk—supplied in the form of an impalpable powder. It is quite simple to prepare, and may be prescribed with confidence in all cases of artificial feeding, from the premature weakling to the normal healthy infant.

The British Medical Journal says:

> *"There appears to be every reason to expect this preparation to prove of great value in the 'hand feeding' of infants."*

Supplied in bottles at 1/9, 3/6 and 7/-

Albulactin

Made by A. WULFING & CO., Amsterdam, Holland.

Supplies for your own dispensing, and for Hospitals, Sanatoria, etc., are available on special terms. Adequate samples for clinical trial sent with pleasure upon request.

A new Collosol Product

CROOKES'
EMULSION WITH COLLOSOL CALCIUM

Special attention is called to this valuable addition to the range of Collosols.

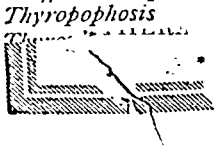
The emulsion itself contains 50% cod liver oil, from livers of cod freshly caught in British waters, and expressed actually on board the trawler, so that otherwise harmful putrefactive processes do not impair the vitamin content.

This vitamin value is verified by laboratory assay, which gives 19/20 blue Lovibond units, or nearly twice as high as that of ordinary cod liver oil.

The combination of Crookes Emulsion with Collosol Calcium is the outcome of the general acceptance that vitamin D affects absorption, deposition and excretion of calcium. Such indications as Rickets are due to an alteration in the absorption of the latter element, and it is obvious that the effects of vitamin D present in Crookes Emulsion will be greatly enhanced by the readily absorbable form of Collosol Calcium.

As thyroid secretions control iodine metabolism, and insulin controls glucose metabolism, so is vitamin D control responsible for the fate of calcium in the body.

Sample supplies obtainable on application will enable practitioners to confirm, from a clinical standpoint, the great value of Crookes Emulsion with Collosol Calcium.



Issued in bottles, 6 ozs. 2/6, 12 ozs. 4/-

SOLUTION

FOR THE TREATMENT OF

ECZEMA & URTICARIA

Dr. Thos. M. Paul, in "The Urologic and Cutaneous Review," Vol. XXXIII, No. 11, 1929, states in the opening paragraph:—

"To state that hives will disappear in fifteen minutes, that the itching and oozing of an eczema will cease in half an hour, and that an eczematous lesion, regardless of its degree of lichenification, will vanish in a few days, as the result of a hypodermic injection, seems preposterous, yet such has been the writer's experience in a series of sixty-one cases."

We have a few copies of the actual article for loan to interested Dermatologists.

COIN OF ANCIENT ARABIA CONTAINING AN INSCRIPTION IN THE CHARACTERS OF A LANGUAGE THAT BECAME AN IMPORTANT VEHICLE FOR THE TRANSMISSION OF CIVILISATION

A considerable body of "classical" culture has come down to us through the medium of the Arabic language, which was taught in the Universities of Europe as early as the beginning of the fourteenth century. To-day about seventy million people speak it in some form. It is not claimed that the pre-Islamic Arabs presented the language thus ready-made to the world, because the language must have been in process of formation during its long unwritten age. The language reached a high degree of perfection, as a consequence, it is said, of poetic contests engaged in at the annual pilgrimage to Mecca.

The coin with Himyaritic characters A.D. c. 150

COPYRIGHT

For the Nervous and Physical Depression of the late Winter Months

℞ Bynin
Amara
Sig 3/p ocrey t.d.s.p.c.

COMPOSITION:

Quinine Phosphate
1½ gr.

Iron Phosphate
2 gr.

Nux Vomica Alkaloids
equal to Strychnine
1/16th gr.

'Bynin' Liquid Malt
1 oz.

Further particulars and clinical trial sample will be sent on request.

ALLEN & HANBURYS LTD., LONDON

Telephone: 3201 (10 lines) Bishopsgate *Telegrams*: "Greenburys Edo London."

Tablets

Digitalis Leaf "A. & H."

Physiologically Standardized

To facilitate administration of standardized digitalis, Allen & Hanburys Ltd. have introduced Tablets Digitalis Leaf "A. & H." These present Internationally Standardized Digitalis Leaf in a particularly convenient form for prescribing and can be completely relied on for maximum and unvarying activity. Each tablet contains 0.033 gramme (½ grain) Internationally Standardized Digitalis Leaf, equivalent to ⅓ of an International unit.

Issued in bottles of 100 tablets.

Leaflet giving further particulars will be sent post free on application

A British Medical Association Lecture

ON

THE DIAGNOSIS AND TREATMENT OF RHEUMATIC HEART DISEASE IN ITS EARLY STAGES.

DELIVERED BEFORE THE NORTH GLAMORGAN AND BRECKNOCK DIVISION

BY

CAREY F. COOMBS, M.D., F.R.C.P.,
PHYSICIAN, BRISTOL GENERAL HOSPITAL.

WE have, I believe, learnt from the study of the rheumatic infection a good deal that is applicable to a comprehension of the general behaviour of infective disease. We have gradually been compelled to realize that this, one of the deadliest forms of disease, is provoked by micro-organisms that do not seem to be radically different from the streptococci that inhabit the normal mouth. Thus we have been once more reminded of the fact that the soil is as important as the seed. A healthy child does not become rheumatic because of any dire bacterial visitation, but because defects of inheritance and of environment combine to lay him open to invasion by organisms that the healthy child is able to resist. It seems certain that in at least a third of all cases this invasion takes place through the tonsils. In this proportion the opening of the campaign announces itself in a frank attack of tonsillitis. What are we to say of the rest? It is probable that in some, if not in all, the infection slips in through the tonsils without exciting any perceptible protest at the site of entry. Some observers think that they have detected gastro-intestinal disturbances which mark a transgression of the lymphoid areas of the bowel by the rheumatic streptococci, but this has not been my experience, though I have been on the look out for these phenomena.

Two-thirds of the rheumatic children appear to be first infected between the ages of 5 and 15, and a large proportion of them are drawn from the elementary school population. We are in the midst of an inquiry into the meaning of these facts—an attempt to find out why these children, and not others, are damaged—in Bristol, with the three neighbouring counties, and as this is not yet complete I shall make no comment, except to remark that so far we have not discovered anything likely to help us in the treatment of the child who is already rheumatic. It would be a great relief to find that these children are infected because of some definite lack or defect, such as an avitaminosis or an endocrine shortage; both of these views have been advocated by experienced observers, and we can only hope that they will succeed in persuading us to agree with them. At the moment, however, we do not seem to have gained anything applicable to the treatment of the rheumatic child from either of these schools.

I am going to assume, in this brief sketch, that the lesions of rheumatism in childhood are provoked by the immediate action of organisms which are themselves present in the injured tissues. The alternative view, that it is the toxins only and not the organisms themselves, does not appear to me to cover all the facts. Organisms have been grown from the pericardial sac, the subcutaneous node, the cerebro-spinal fluid, and so forth; and if we accept any of the bacteriological evidence about the disease we must also accept these findings. There is, then, an actual bacteriaemia.

About the lesions we are in no doubt. The principal tissues attacked are the heart, the joints, the meninges, and the subcutaneous tissues. Recent workers have shown that the lesions are more widely scattered than we used to teach. I may refer you to a recent paper by A. F. Bernard Shaw[1] as an illustration of these newer views, to the work of Nash and Fraser on the pulmonary lesions of acute rheumatic infection, and also to Vincent Coates's papers on the prevalence of small subcutaneous nodules in these children. The damage done is therefore more widely diffused than was at one time thought.

Another fact that is more and more impressed on me by extended clinical and pathological observation is the persistence of the infection. Formerly we thought of the course of the disease in terms of a series of periods of activity, separated by intervals of quiescence. I am learning to think that these intervals, during which there is neither fever nor any other clinical sign of active infection, are nevertheless spent by the infective agent in a kind of subdued but not suspended animation. In order to unmask these activities Dr. Perry[2] has conducted a series of observations on the leucocyte picture of rheumatic carditis in childhood, but without discovering any change that we can depend on to betray the presence of progressive infection. What one notices as undeniable proof of this progress is that a child whose general condition is fair, his temperature normal, his cardiac signs unaltered, is nevertheless found after a period of apparently uneventful weeks to have definitely worsened, and the heart, examined post mortem, if this deterioration should end fatally, displays unmistakable proof of infection which must have been active for weeks before death.

These two new lessons, then, we have to assimilate: the infection is more widespread and also more persistent than we had supposed. We may perhaps limit ourselves here to a brief notice of the cardiac lesions. These are manifestly distributed along the course of the coronary arteries and their finer ramifications, so that we meet them wherever we look in the tissues of the heart, whether in the pericardial covering, the endocardial lining, or the myocardial mass. It is by their action on the muscle itself that the bacteria of rheumatic infection involve their victim in immediate danger; for example, on the day of writing I was told of a child who had died in the hospital, within a week of the onset of his illness, with acute ventricular dilatation and failure. Many of those who escape this fate survive for a few years only, and then succumb to a recrudescence of the infection, which deprives the ventricular muscle of such little margin of safety as had been spared to it by previous activities. Of those who are more fortunate than this, a majority pass on into a condition of permanent valvular disease which has the effect of limiting the scope and length of life. What is to prevent this? Can it be in any way prevented? Some years ago, when Dr. Poynton[3] consented to write an introduction to the book of which I have already spoken, I was greatly struck by one comment which he made, to the effect that an interesting result from the following up of a group of cases of undoubted early cardiac rheumatism was the discovery that a quarter of them lost all signs of the disease in fifteen years. Dr. Poynton went on to say that this was in accord with his own experience. He had known recovery from undoubted carditis so complete as to throw doubt on the validity of the original diagnosis. "Such facts," he concluded, "are very comforting to those who believe in the future of prevention."

Now, since this was written we have in Bristol had over two years' experience of a cardio-rheumatic clinic. In that period we—Dr. Perry and I—have seen 1,100 children referred to us by the school medical service for an opinion on the state of the heart. Of these, 653 have been judged by us to be suffering from rheumatic heart disease. I can give you no statistics in support of the statement that this organization is doing good in the arrest of the disease in an appreciable proportion of these children; yet I am convinced that this statement is true, convinced enough to derive encouragement for the prosecution of a campaign against an enemy that sometimes looks invincible. Now there is no secret or special means by which this progress is achieved. It depends on the same principles as those which ought to guide us in the fight against all infections—early diagnosis and persevering treatment.

If rheumatic injury to the heart is to be recognized in an early stage, it can only be done by remembering that symptoms of cardiac insufficiency do not appear till the lesions are already established and severe. This is merely an illustration of two great principles of pathology: the first, that no lesion of any organ can be considered apart from disease in the rest of the body; the second, that in

every vital organ there is so wide a margin for emergencies that symptoms of imperfect function do not appear till the disease has been in progress some time, long enough to encroach seriously on that margin. If we apply these principles to the consideration of rheumatic carditis, we shall note, first, that hints as to the possibility of rheumatic infection of the heart may be furnished by symptoms of other rheumatic phenomena; and second, that constitutional symptoms are likely to precede those which indicate a decrease in the mechanical efficiency of the heart.

Coming to details, we may say that there are four different approaches to a diagnosis of cardiac rheumatism in its early stages.

1. The easiest of these is that in which the rheumatic infection declares its presence within the body by provoking either arthritic pains or chorea. Even this is not always as easy as it sounds. Sometimes, for example, an attack of what looks like acute rheumatism turns out to be something else, such as osteo-myelitis. More often, however, the joint pains themselves are so trivial that the child makes but little complaint, and that little receives no notice. One cannot but feel some sympathy with this point of view. We do not want to encourage children to make a fuss over every little ache or pain, and it is not easy to tell parents how to lay stress on the pains that matter, while ignoring those that do not. Perhaps one might say this: that pain persisting more than a day, or pain which makes the child lame, ought to be noticed; also that if the child looks ill or has a rise of temperature, however small, with the pain, the doctor ought to be called in.

Then, again, supposing there is no doubt as to the rheumatic nature of the illness, how are we to know whether the heart is damaged or not? On this point I am inclined to say that every child who has rheumatic polyarthritis that can be recognized as such may be assumed to have an infected heart also, even if there are neither symptoms nor signs of this. I cannot recall any example within my own observation of a child who passed through an attack of articular rheumatism without showing either at the same time, or later on, evidences of cardiac rheumatism. With chorea it is different. Many children develop, sustain, and recover from an attack of chorea without displaying any evidence of cardiac infection. It is to be remembered, however, that if these more fortunate ones be followed up, a considerable proportion will be found later to exhibit signs of cardiac infection. Of the other rheumatic phenomena I need say little, except to remind you that the subcutaneous node is always to be regarded as a proof that the body is heavily infected. If these nodes are found, therefore, it must be assumed that carditis is sure to develop also, and that it is likely to be severe.

2. Rheumatic carditis is so often preceded by an attack of tonsillitis that one ought to consider repeated examination of the heart (and also, one may add, of the urine) an essential part of the care of any child with inflamed tonsils. It is not enough to do this throughout the attack of tonsillitis itself. Often the signs of cardiac inflammation do not appear till a week or more after the tonsillitis and its constitutional symptoms appear to have died down. If possible, therefore, one ought to see children convalescent from tonsillitis a few days after every obvious symptom has cleared up.

3. The most important of all these methods of securing an early diagnosis of cardiac rheumatism is that which it is hardest to practise and easiest to forget. It turns on the fact that the heart may become definitely and permanently damaged by rheumatic infection without any other perceptible manifestation of the infection. It is perhaps putting it too strongly to say that one ought to think of carditis as the disease, and arthritis, chorea, and so on, as the complications. That is not a true account of the pathology of this infection, which ought rather to be looked on as causing four chief manifestations: carditis, polyarthritis, chorea, and nodes. Yet from the point of view of their ultimate importance these other phenomena are almost negligible. Their real significance is that of indicators warning us of the possibility—indeed, as we have seen, of the probability—of a concomitant carditis. The particular difficulty that we are now discussing is that of the child whose heart is infected before these other phenomena have developed; indeed, in many cases they never develop at all, and the cardiac lesion is not found until the chest is examined, either as a result of some other illness or in the course of a routine inspection such as that of the school medical service. The work of which I spoke just now has convinced me that this group of cases is a large one. During the same period that has brought to light in the elementary schools a total of 653 cases of cardiac rheumatism we have been receiving, through a system of voluntary effort, reports of cases arising in the private practices of medical men within the area under review. In Bristol we have had 238 of these cases reported, and I do not believe that many cases have escaped detection either by the medical men who have so kindly furnished these reports or by the school medical officers. It seems, therefore, as if for every case of rheumatic carditis that makes itself known to a medical man at the time when it is established there are two that are not found until the child is examined as a part of the school routine. This is a serious state of affairs, and I shall make some observations on it again presently. Here let me say only this, that the earliest symptoms of such cases are not cardiac but constitutional—loss of appetite, vague seediness, increasing pallor, and, above all, loss of weight. The practical lesson to be learnt is that every child brought to us for these vague symptoms must be stripped and examined thoroughly. I do not say that this will do away with the delay in diagnosis that results in the establishment of serious disease before its presence is first recognized. It would, however, reduce appreciably the numbers of these overlooked lesions.

4. Finally, there are a few children to whom we are first called because of cardiac symptoms. These fall into two groups. First, there are children who are taken with an acute febrile illness with chest symptoms. Not infrequently the first diagnosis made is that of pneumonia or pleurisy, and it is only after a few days that the development of a pericardial rub, or a rapid widening of the area of cardiac dullness, teaches us to look to the heart for an explanation of the illness. Then there is another group of children who are brought to us because of breathlessness. This is a very small group. It takes a severe degree of cardiac disease to make a child visibly breathless. We may say, therefore, that whether the carditis is acute or chronic it must be severe if it is to produce symptoms of cardiac insufficiency, and it would therefore be a grave mistake to regard such symptoms as essential to a diagnosis.

To sum up what has so far been said as to the possibility of an early diagnosis: We ought to examine thoroughly every sick child that is brought to us; we ought to examine early, thoroughly, and repeatedly every child with tonsillitis; and we ought to regard as a probable cardiac victim every child with any definite manifestation of rheumatic infection.

Before we leave this subject of early diagnosis you may be interested by a few observations on the physical signs which may be relied on to indicate to us the existence of a carditis. As in so many of our attempts to make an early diagnosis of visceral disease, we have to steer a narrow and difficult course between two dangers—that of overlooking the lesion, on the one hand, and, on the other, that of being deceived by some counterfeit.

My first point is that arrhythmia in a child means nothing unless it is supplemented by signs of serious organic heart disease. An exaggeration of the physiological sinus irregularity is seen in most children at one time or another, and particularly during convalescence from an acute illness. To regard it as a sign of cardiac disease is therefore a serious mistake. It is true that very rarely one sees the total arrhythmia of auricular fibrillation, and more rarely still arrhythmia due to abnormalities of auriculo-ventricular conduction, in children with rheumatic heart disease; but this is only in the presence of very acute or serious phases of the disease. We may therefore take it that arrhythmia alone is not to be accepted as the basis of a diagnosis of organic heart disease in childhood.

It is almost as true to say that a murmur alone is not to be regarded as evidence of cardiac disease in childhood.

There is one exception to this—the diastolic murmur of aortic incompetence may, very rarely, be the only sign of cardiac disease in a rheumatic child. Even this exception is so rare that we might almost accept my dictum as it stands. If we amend it to run thus, "A systolic murmur alone is not to be regarded as evidence of cardiac disease in childhood," we shall not be overstating the case. The earliest phase of cardiac rheumatism that can be diagnosed with absolute confidence is that in which there is a coincidence of four physical signs: increase in the area of impulse in the leftward direction; accentuation of the first sound at the apex; a systolic murmur limited to, or at all events maximal at, the apex; and an accentuation of the pulmonic second sound. To make a diagnosis in the presence of these signs is an easy matter. Even if there is no rheumatic history and the child is free from symptoms of any kind at the time, the discovery of these signs justifies a diagnosis of cardiac rheumatism.

What is not so easy is a right decision as to children who display part only of this picture. There are two principal groups exemplifying this kind of difficulty. Among children of school age systolic murmurs are very common. Sometimes they are heard at all parts of the precordium; sometimes at basic areas only; sometimes at the middle of the precordium, at the inner end of the fourth left space; sometimes at the apex only. I wish there were time to discuss all these in detail, but this alone would occupy the whole of our available time if we were to do it thoroughly. It is a little disturbing to find how much uncertainty still surrounds the explanation of so simple a physical sign as *the systolic murmur. Those of you who would like to read* something more of the systolic murmurs heard in childhood will be interested by a paper published in the *Archives of Disease in Childhood* by Dr. Dunstan Brewer.[4] This includes some valuable observations on the course of murmurs of the "doubtful" or "haemic" type, which showed that a majority were found to disappear if the children were re-examined over a period of years.

All that I need add here to the general dictum as to the unwisdom of making a diagnosis of organic disease on the strength of a systolic murmur alone is that, first, a murmur heard at the apex alone, even if unsupported by other signs, justifies a waiting attitude; and also that, even if the murmur is general, heard all over the heart, this also may be regarded with suspicion if it arises in the appropriate circumstances—for example, after an attack of tonsillitis or in a child with chorea. Speaking generally, the younger the child the more likely are these signs to prove evanescent. When they appear in a child of 10 or more, suspicion is more likely to pass into certainty. But, even so, we are *not often justified, I think, in keeping a child in bed on* the strength of the murmurs alone.

There is one little point that I think worthy of notice in relation to this question of systolic murmurs, and that is their reaction to a change of position. I find that it adds very little to the time spent in an examination to observe this, if it is made a matter of routine to examine the child standing up first, then *lying flat on his back*, then lying on his left side with the heart underneath. The value of this routine lies in the fact that many organic murmurs heard at the apex are inaudible when the patient is standing, but are brought out clearly when he lies down flat, and even more so when he is on his left side.

There is much more that might be said about these murmurs, but I must devote a few moments to a consideration of the value of the other signs. Let me put it briefly thus—that an increased area of impulse by itself, even without alteration in the sounds, is to be treated with respect. If it is noted in a child who, there is reason to think, is the subject of recent and active infection, it is enough to impose on us the duty of keeping the child in bed, or on light exercise, till we are satisfied that evidence of active infection is at an end. If it is found in a child who gives a history suggestive of previous though extinct rheumatic infection, it is a reason for re-examination from time to time over a period of twelve months at least. These precautions are all the more necessary if there are changes in the sounds—*accentuation of the first sound at* the apex or of the second sound at the pulmonary base; or doubling of the second sound at the apex. I do not think we are called upon to regard these signs as evidence of a definite carditis, as it is clear from the course of a group of 34 cases of this *kind*—cases that I *labelled* "doubtful and suspicious"[5]—that the odds are against their evolution into serious organic disease. Of these 34 cases, 15 lost their signs entirely, 11 developed a permanent valvular fibrosis, and 8 remained unchanged after a period of observation varying from five to fifteen years.

I find I have been betrayed into the very thing that I wished to avoid—I have said a great deal more about physical signs than about symptoms. It will be found that under the present conditions of practice the children that we see are those with symptoms. I wish it were possible to take a leaf out of the school medical service books, and get every child, whether ill or well, examined periodically by the family doctor. This may seem an absurd dream as things are at the moment, but I believe it is not altogether outside the purview of practical politics.

Let me in conclusion devote a few minutes to a consideration of the principles of treatment of rheumatic heart disease detected in an early stage. It may help to illustrate some of these principles if I mention that, of the 653 children with rheumatic heart disease seen in the clinic to which I have referred, we have allowed two-thirds to continue attendance at school. More than half of these are allowed to attend only under restriction of exercise. Our reason for asking for this restriction is not that we fear mechanical overstrain of a damaged heart. We restrict exercise in rheumatic infection of the heart just as we should in any other persistent infection, because we want the child to devote as much as possible of his physical energies to his fight against the infection. If their exercise could be adequately supervised I am sure it would be possible to give them a freedom in this respect that, under present conditions, seems imprudent; for the principle that underlies all our ideas as to treatment is that we are dealing with a disease in which periods of activity alternate with periods of quiescence. During quiescence restrictions are not necessary and may even be harmful; while during the active phases the degree of treatment ought to be proportioned to the degree of activity. We are cautiously beginning to employ *supervised exercise in convalescent cases.*

Complete rest in bed is only advised in about a tenth of the cases that come to us in the clinic. This we advise whenever there is any symptom of active infection, such as fever, wasting, joint pains, or chorea—at all events at first. We shall probably increase the proportion of children recommended for institutional treatment if and *when the accommodation can be found. This period of* rest not only gives the patient a better chance of overcoming his infection; it also gives the doctor a better chance of assessing the degree of activity and deciding what to do. If the child shows continued signs of activity, or if the initial symptoms of infection are severe, prolonged rest is needed, even up to six months in bad cases. The symptoms that make me most anxious, and therefore most insistent on the need for prolonged rest, are continued pallor and wasting, fever, nodes, chorea, recurring joint pains, and progress in the definition of the physical signs.

One might enlarge on the significance of fever in this disease, but there is only time for one or two points. Two kinds of fever are seen in this disease. Sometimes an otherwise normal temperature is disturbed by periods of pyrexia varying from two or three days to as many weeks. These mark outbursts of infection so severe that they are not likely to be overlooked. The other kind of fever is more insidious. The child shows an excessive daily fluctuation rising but little above the normal line, but persisting for weeks. This is associated with progressive injury to the cardiac tissues of a very damaging kind. In other cases, again, the absence of fever by no means proves an absence of active infection. Some of the worst cases run an afebrile course, which is perhaps a sign of unusually poor resistance. In such cases there is *generally abundant evidence that matters are not going* well; the child remains pale and thin, the cardiac signs

are either stationary or ingravescent, and there are hints of circulatory failure such as faint cyanosis, increase in the size of the liver, puffiness under the eyes, and so forth. Fever, then, is not an infallible guide in the treatment of this disease. In search for some other guide Dr. Perry has made an extensive inquiry into the value of leucocyte counts, but here again we have been disappointed, as I have already said. It will be seen, therefore, that we find it impossible to lay down any rules as to the duration of rest in bed in this disease. What I would suggest is that any febrile event of more than four days' duration indicates a subsequent rest of not less than four weeks. Return to activity after this must be gradual and tentative, and conditioned not only by what has happened during the period of rest, but also by the child's response to increasing exercise.

About the use of salicylates there is a wide diversity of opinion. It is useless to weigh the pros and cons here, for the evidence is so misty and inconclusive. My belief is that it is practically always safe to give salicylates in big doses. Occasionally—in perhaps one case in a hundred—you find that it is doing harm, and then, of course, it must be stopped. Often it will be found that it is not doing good. Sometimes this is because the dose is too small, and sometimes again it is worth while to substitute some other preparation—for example, aspirin may suit a particular child better than the sodium salt. We find that 5 to 10 grains of the former, or 10 to 20 grains of the latter, seldom cause toxic symptoms, even if given every hour or two hours for more than a day at a time. We have tried all sorts of other plans designed to kill off the infection, for this, I suppose, is the way in which the salicylates act; but we have not found anything that can be proved to have the desired effect, and I am not going to weary you with a catalogue of our failures.

Similarly, we have experimented with many means of enhancing the child's resistance, without much success. I feel sure that when the periods of rest are conjoined with free access to fresh air and sunlight, and with a liberal diet in which fats are given generously, the child gets on better. We have lately found it well to give cod-liver oil and iron to children even while they are still taking salicylates, and this I believe is worth bearing in mind. Tonsillectomy is thought by many experienced observers to be indicated as a routine measure. The evidence for and against this view is very difficult to appraise, and there is no time to attempt it here. Our own practice is to have tonsils removed if they are obviously diseased, if there is an associated adenitis, or if by reason of their size their removal would be indicated even apart from the coexistence of rheumatic infection. More than once I have seen a severe recrudescence of the infection follow an excision of tonsils which have recently been the seat of an acute inflammation, and it seems, therefore, that anything of this kind should be allowed plenty of time to settle down before operation is advised.

This account of treatment is very unsatisfactory, and seems to amount to nothing more than watching the course of a disease which we are powerless to arrest. Yet I feel sure that much is achieved merely by patience and perseverance in those homely measures by which we are accustomed to encourage the fight against bacterial activity. What we need is a clear realization of the tenacity and persistence of this infection. It is not a matter of days or even weeks, but of months or even years. One of the fruits of this attitude of mind is the increased provision for prolonged institutional treatment of these children, but even where this is not essential, or is impracticable, the mere fact that we realize the need for patience and perseverance in the application of an enlightened common sense to the management of this disease is going to make a sensible reduction in the number of cripples for which it is responsible.

An Address ON THE DIAGNOSIS OF EARLY JUVENILE RHEUMATISM.*

BY

REGINALD MILLER, M.D., F.R.C.P.,

PHYSICIAN, AND PHYSICIAN IN CHARGE OF THE RHEUMATISM SUPERVISORY CENTRE, PADDINGTON GREEN CHILDREN'S HOSPITAL, LONDON.

JUVENILE rheumatism is an environmental disease, and until the mass production of it can be stayed by public health measures the best contribution to the problem which can be made by us as individual clinical physicians is to get each separate case of rheumatism in a child diagnosed, treated, and under supervision at the earliest possible stage of the disease. It is to this matter that I now direct attention, and I emphasize at the outset that the diagnosis of early rheumatic infection in a child is at least as difficult a matter as that of early tuberculosis.

Two preliminary questions arise. First, have we a chance of diagnosing rheumatism before serious harm has occurred in the child's heart? Secondly, if we do make such an early diagnosis, have we a sporting chance of preventing serious heart disease?

In answer to the first question it is undoubtedly true that we have a chance of early diagnosis. However abrupt the onset of a serious attack of rheumatism may appear to be—and we all know how rapid, how ruthless, and how overwhelming the onslaught of rheumatic infection can be—it is almost invariably the case that premonitory symptoms have preceded the attack for weeks or months, and that they have been overlooked, neglected, or misinterpreted. Those who doubt this have not taken their clinical histories correctly; in nearly all cases there is this premonitory stage. And if we make a diagnosis in this premonitory stage, shall we have a chance of preventing more serious attacks, particularly the more serious forms of heart disease? Frankly I do not see why we should doubt it. It is in line with what we do in other diseases. We can remove foci of infection, combat the environmental factors, and protect against exciting causes of acute attacks. Sometimes we shall fail; perhaps we start too late, perhaps the environment is too heavily against us, perhaps there are factors we cannot control or even recognize, but I see no reason to doubt that often we do really help. Some require mathematical proof of this: they will not get it; you cannot make a statistical comparison of known results with unknown possibilities. The real proof comes to the clinical worker who is supervising his own patients. When he sees, as I have seen in dozens of instances, the removal of tonsils and the adoption of other measures lead to increased weight, strength, and colour, and the gradual loss of rheumatic pains, he will not doubt that in a certain proportion of cases he has actually prevented serious rheumatism and heart disease.

EARLY DIAGNOSIS.

Before I come to the study of the prodromal symptoms of juvenile rheumatism there are two factors of possible diagnostic value to be considered—the rheumatic diathesis and the so-called pre-rheumatic child. Are these realities? Can we recognize them? Are they an aid to diagnosis?

The Rheumatic Diathesis.

Some recent writers have professed great faith in the rheumatic diathesis, in the sense that they think that certain children, if they lose good health, turn naturally into cases of rheumatism. I do not share this view. The older physicians laid great stress upon the familial tendency towards rheumatism, and this rather tended to a belief in a rheumatic diathesis. Recent investigations, undertaken on very accurate and strict lines, show that the family tendency has been exaggerated and is not more than can be accounted for by the frequency of the disease and

* Delivered to the Hull Division of the British Medical Association.

the environmental causative factors. Naturally where a disease is very common and is powerfully predisposed to by environment, its incidence in families will be high. Several points can be adduced against the view that a rheumatic diathesis is of moment. Does a diathesis, for instance, show a class incidence as juvenile rheumatism does? Again, we must bear in mind the Poor Law residential schools. Here thousands of children from the rheumatic stratum of the population in urban districts, in whom there is not the slightest doubt that dozens of cases of rheumatism would have developed had they been left in their own homes, live year in and year out without a case appearing amongst them. How does this happen? Have they left their diatheses at home? Clearly, we need not go in fear of the rheumatic diathesis.

The Pre-rheumatic Child.

As a clinician I have even less liking for the term "pre-rheumatic child" than for the "pre-tuberculous child." These are administrative labels and have little to do with the realities of clinical medicine. It is difficult for us to envisage a condition which is all prognosis and no pathology. However, the term has come into use, and I can only give it as my opinion that the pre-rheumatic child as described is the ordinary rheumatic child, and that there is nothing "pre" about it, save that it has not yet suffered a knock-out attack of the infection. It is in the stage when repeated minor infections are wearing down the child's resistance and so paving the way to a major attack.

Is there, on the other hand, a pre-rheumatic child in the proper sense—namely, a child whose resistance to streptococci is lowered, though not by repeated minor rheumatic infections? The post-scarlatinal child ought perhaps to be reckoned as this, but apart from this I cannot say that I can recognize such a child. Some have endeavoured to associate intestinal indigestion and toxaemia with future rheumatism, but for my own part I do not consider the case proven. It is true that early cases of rheumatism suffer sometimes from intestinal dyspepsia, but in my experience the really bad cases of intestinal toxaemia are not prone to develop juvenile rheumatism. Nor are, perhaps it is as well to add, the ordinary cases of enlarged tonsils and adenoids.

Premonitory Symptoms.

I have already said that in most cases of acute rheumatism in children there is a prodromal stage lasting for weeks or months before the onset of severe symptoms; and that this is due to the method of invasion by the infecting micro-organism. Both clinically and histologically we have proof that the invasion by rheumatism is by means of repeated minimal infections, which ultimately may wear down the child's resistance and so result in an acute attack. It is the symptoms in this prodromal stage that we now have to study, and for this purpose I define the prodromal stage as that of rheumatic infection before an attack severe enough to send the child to its bed.

Let me emphasize one important aid that we have to the study of the child in the prodromal stage of rheumatism—namely, the convalescent rheumatic child. As a child recovers from an acute attack it passes back into a condition similar to that it was in during the prodromal stage or stage of invasion. We cannot therefore study the convalescent child too carefully from this point of view.

In studying the premonitory symptoms of juvenile rheumatism, or rather the child in the prodromal stage of that infection, four groups of symptoms may be usefully described; but I want to make it clear at the outset that not every child who could be included in any of these four groups is rheumatic, only that it is out of these groups that you will get your rheumatic cases.

1. *Constitutional Symptoms.*

Juvenile rheumatism is the result of a generalized systemic infection, but its slighter and earlier symptoms are for the most part due to a general rheumatic toxaemia. Consequently there is a condition of general constitutional ill health, not in itself very specific or diagnostic, but recognizable by its association with the rheumatic symptoms to be described later. The chief importance of this state of ill health, and the reason why it must be carefully studied, is that, unless the occurrence of definite rheumatic symptoms is inquired into, it may easily be mistaken for some other condition.

The rheumatic child is pale, rather sallow, and unhealthy in appearance. Its most prominent symptom is its tiredness. Its appetite is poor, its nerves irritable, its sleep not too good. Often it is a little short of breath, and may have a throat cough. Its temperature and pulse rate may be raised by evening. Perhaps the only thing characteristic about its appearance is the flush which appears on the cheeks in a hot room; there is in this a *rather typical mauve tinge in the pink flush.*

Now a child who looks toxic, who is pale, tired, off its food, and running a little fever at night, is not unlikely to be regarded as tuberculous. Add to these symptoms a cough from the presence of septic tonsils, and slight shortness of breath from myocardial poisoning, and the similarity to the symptoms of early pulmonary tuberculosis becomes even greater. It must be emphasized that the symptoms which in a young adult should suggest the possibility of consumption do not necessarily, or even usually, mean the same in a child. This is important, for although it is bad for a rheumatic child to remain undiagnosed, it is still worse for it to be diagnosed as tuberculous. The diagnosis between the two types of child is not as a rule difficult: the appearance of a rheumatic child is very different from that of a tuberculous child, and in cases of difficulty the occurrence of typical rheumatic pains may be a decisive point.

2. *Throats and Pains Group.*

This is the most easily recognizable group. Sore throats are common enough in rheumatic children, but they may be absent where the tonsils are small and buried—a type which is associated in my mind with ultimate mitral stenosis. Not much is heard in children of the persistently uncomfortable throat, such as is complained of by adults with septic buried tonsils. Of much more importance than the symptom of sore throat are the signs of tonsillar infection. Septic tonsils are present in 80 to 90 per cent. of rheumatic children, and spontaneous cure in them is very exceptional. In my own cases not 5 per cent. of tonsils thought at one time to be infected have later been passed as normal, and these would consist chiefly of examples of acute tonsillitis.

What criteria shall we adopt as indications of chronic tonsillar sepsis? It is worth while spending a moment on this matter. (1) The size of the tonsil does not matter. The tonsils in rheumatic children are seldom very large, and do not often cause real obstruction; indeed, they may be very small and buried. (2) The surface of the tonsils is red in acute phases, and cryptic and irregular in chronic cases. (3) The faucial pillars show crescentic areas of red where they cover the buried parts of the tonsils. (4) The tonsillar glands at the angles of the jaw are enlarged. (5) Purulent material can be squeezed from the mouths of the crypts.

These signs are not all of equal value. I do not know, for instance, that we have any right to insist that the tonsillar glands should always be enlarged in rheumatic tonsillitis, for we are well aware that lymphatic glands in rheumatism do not swell and do not seem to put up any barrier to the infection. Again, I do not personally know how much stress should be laid upon the appearance of purulent material from the crypts when the tonsil is squeezed: does it necessarily mean a chronic infection capable of harming the child? Therefore I lay the greatest stress on the reddening of the faucial pillars. This last is applicable to the buried as well as to the visible tonsil; it shows infection of the hidden part of the tonsil, and it means that that infection is active and sufficiently virulent to be producing a reaction outside the tonsil, and so is presumably capable of poisoning the child to some degree.

Rheumatic pains are so well known that they may be considered briefly. Their characteristics are that they occur in the neighbourhood of joints, that they are made

better by rest and worse by exercise, and that they may be accompanied by slight fever. They may be sharp or more in the nature of a dull aching pain. We cannot possibly maintain that all muscular pains in children are truly rheumatic. Delicate nervous children with intestinal toxaemia, acidosis, and vasomotor disturbances get similar pains, and therefore in diagnosis the whole picture of the child has to be taken into consideration. Pains in the arms, wrists, and fingers are usually rheumatic; and the same may be said of stiff neck, in the absence of enlarged glands.

In this group with sore throats and pains a certain number of children will develop serious rheumatism, usually arthritis and heart disease, with perhaps nodules. The association between tonsillitis and chorea is less close than that between tonsillitis and arthritis.

3. *The Nervous Group.*

Rheumatism is a nerve poison. When it damages the brain with sufficient severity, by toxaemia or infection, we get the syndrome which we know as chorea; but long before this condition is reached there is clinical evidence that the nervous system is affected in rheumatism. No child with any degree of rheumatism fails to show some symptoms referable to the brain; there is much truth in the saying attributed to a physician of the last generation that "all rheumatic children have chorea, only some more so." For this condition I suggested many years ago the term "latent chorea."

The fundamental change which occurs is that of general nervous instability. The child becomes sharpened up; it is quick, responsive, excitable, emotional, and easily depressed or excited. It smiles at you readily and its hands are rather fidgety. These attributes make it very friendly and explain why the rheumatic children are so popular in hospital. They also explain why such children do so badly at convalescent homes.

Engrafted on this general nervous instability of rheumatic origin may be other disorders which we usually class as functional—sleeplessness, sleep-walking, night terrors, nocturnal enuresis, ties, and so on; and the point which I wish to make is that a certain number of rheumatic children will come first under observation on account of such disorders; or, put the other way round, a proportion of cases seeking treatment for various functional nervous disorders will be instances of rheumatic infection.

The association between rheumatism and general nervousness is well recognized. I used to be taught that nervous children were particularly prone to rheumatism. I am sure this is the wrong way round: a child does not become rheumatic because it is nervous, it becomes nervous because it is rheumatic. There are, of course, many children who conform to this group who are not rheumatic; nevertheless it is out of this group that many cases of rheumatic infection, chiefly chorea, will develop.

4. *The Cardiac Group.*

I come now to the consideration of those signs in a heart which make one suspect rheumatic infection. Sometimes, as we all know, in an individual case the condition of the heart is the one and only diagnostic proof of rheumatism. More often we search the heart for signs of rheumatism to confirm a suspicion of the presence of the disease. In examining the heart of a child for such evidence it is absolutely essential that the examinations should be made when the patient is lying down as well as when he is standing up. Frequently, too, it is well to auscultate the heart with the child lying on its left side.

The signs suspicious of rheumatic heart disease, starting with the least important, are as follows: (1) Increased pulse rate. This is of no diagnostic value unless accompanied by (2) dilatation of the left ventricle—that is, the apex is outside the nipple line. Such a condition probably means the presence of myocarditis, and is therefore suspicious of rheumatism. (3) If with enlargement of the left ventricle there is an apical systolic murmur, audible in any of the postures already mentioned and clearly not a cardio-respiratory bruit, the diagnosis of rheumatism is practically certain. (4) The presence of a reduplicated apical second sound, or of a mid-diastolic apical murmur, is also good evidence of rheumatism. This "third sound," as it is called, requires careful listening for; it is audible over a very small area internal to the apex beat, and is usually more clearly heard when the child is lying down than when it is standing.

In addition to these changes, which are the ordinary ones found in early rheumatic heart disease, there are certain cases of rheumatism which present themselves as examples of persistent tachycardia. In such instances it may be very difficult to distinguish the neurotic from the toxaemic group, and it is therefore well to remember that certain of the cases of persistent tachycardia met in children will ultimately be found to be of rheumatic origin.

SUMMARY.

Now I have been through most of the early signs and symptoms of rheumatic infection in a child. It will be seen that they are very various, and for the most part slight and rather indefinite. It is this that makes the diagnosis of early rheumatism difficult. It can only be reached by the due consideration of all the signs and symptoms. Where there are several such, even though each one separately is no more than suspicious, a positive diagnosis may be reached with some certainty. For my own part I think the diagnosis is most easily reached in two stages: first, by a consideration of the general appearance and deportment of the child, often enough very characteristic to one familiar with rheumatic children; secondly, by a detailed consideration of the various signs and symptoms, including a careful examination of the heart.

RADIUM TELETHERAPY.

NOTE ON THE APPARATUS AT PRESENT IN USE AT THE WESTMINSTER HOSPITAL WITH FOUR GRAMS OF RADIUM.*

BY

FRANCIS ROCK CARLING, B.Sc.LOND.,

TECHNICAL ADVISER FOR RADIUM WORK, WESTMINSTER HOSPITAL.

THE apparatus to be described was designed at the Westminster Hospital to meet the problem of making the most effective though economical use of the 4 grams of national radium that had been lent to the hospital for use as a "bomb," and, at the same time, of protecting from the emanations all persons except those actually under treatment.

The difficulties of affording proper protection were much simplified by housing the bomb in one of the theatres, which happens to be so situated that below it is a stairway, while above there is an open space, and on each side are two main walls and an area that must be traversed before reaching the wards. It was then anticipated that, by limiting the radiation to an approximately vertical direction, complete safety would be assured. Subsequent investigation by the usual electroscope method showed that the amount of radiation that could be received from the bomb by anyone in the hospital, other than those attending in the bomb room, had no biological significance.

The apparatus is constructed so that two patients may be treated simultaneously, one above and one beneath the radium container (Fig. 1). The lower stretcher is placed as close to the ground as is convenient in order that the upper stretcher shall not be so high as to offer great difficulty of access. Each stretcher can be raised, lowered, and traversed longitudinally and laterally, and the lower stretcher can be tilted as well. The stretchers run on wheels, and can easily be moved to and from the bomb.

The radium is held in twenty containers arranged in four groups of five; each group can be withdrawn from use, if required, by pulling the appropriate knob provided outside the bomb (Fig. 2). When not required the radium is all withdrawn so that it is buried in lead. The average protection provided, whether the radium is in use or withdrawn, amounts to some six inches of lead in the horizontal plane, and, when withdrawn, to three inches on the neutral axis. When the apparatus is in use the radium sources are

* See *British Medical Journal*, May 11th, 1929.

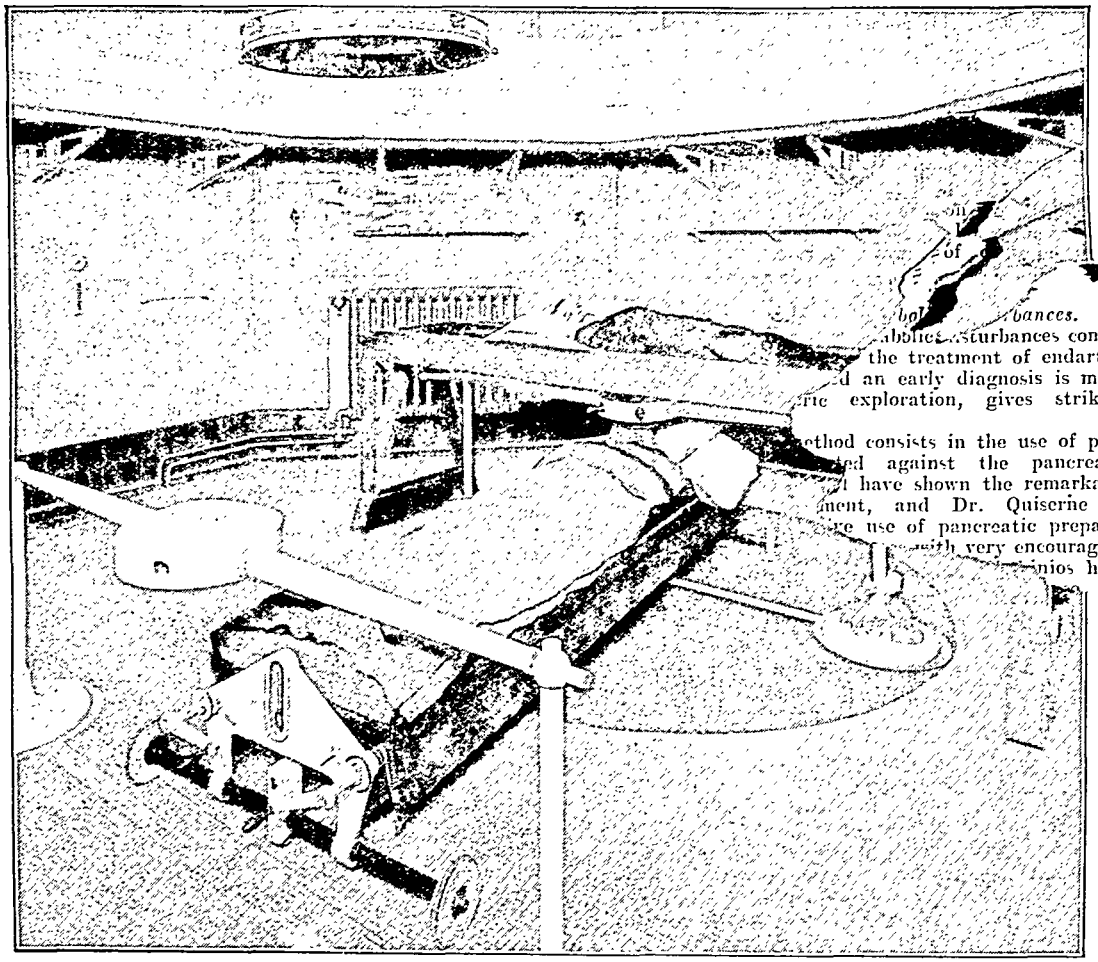

FIG. 1.—The apparatus in use.

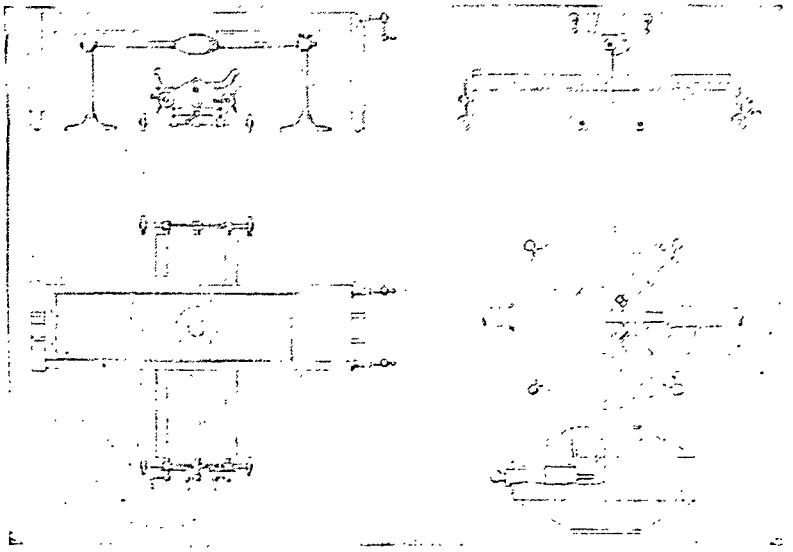

FIG. 2.—Side and end elevation, and plan of apparatus. Detail of container.

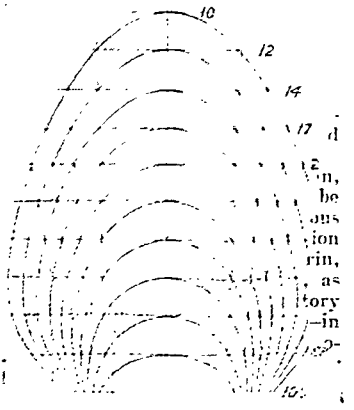

FIG. 3.—Iso-intensity curves in air [illegible] diagonal between two sources.

approximately at the corners of a four-inch square. The separation of the sources reduces the skin intensity and flattens the isodose lines, while only slightly reducing the intensity at a depth. In the upper and lower face of the container is a circular recess six inches in diameter, four holes in the bottom of which expose the radium. Into these recesses can be inserted lead plugs having various openings, which to some extent control the dimensions of the "radiant beam." The bomb can be tilted about one axis. The screenage, amounting to the equivalent of just over 1 mm. of platinum, consists of monel metal, brass, aluminium, and wood.

So far charts of the "radiant beam" have been obtained experimentally in air, but for various technical reasons charts of the "radiant beam" in tissue are not yet available.

The procedure is as follows: The radium being placed in its container, the patient lies at the end of the room most remote from the bomb. Rheumatism is a nervous disease, and before this condition is reached the best position can be got with sufficient severity, the syndrome which we know as "rheumatism" which is on the way to that the nervous system is affected—whether is then moved on to the actual radium is effected. When both child with any degree of rheumatism is symptoms referable to the brain the saying attributed to a physician is put into the working that "all rheumatic children have of exposure to the radiation. so." For this condition 1 hour to be in the room during the treatment term "latent rheumatism" is the fun itself as far away from the radium as possible, and never further protected by a lead shield.

ENDARTERITIS OBLITERANS OF THE EXTREMITIES.

A DISEASE OF METABOLISM.

BY

A. P. CAWADIAS, O.B.E., M.D.DURH. AND PARIS, M.R.C.P.LOND.,

FORMERLY CHIEF OF MEDICAL CLINIC, BEAUJON HOSPITAL, PARIS, AND SENIOR PHYSICIAN, EVANGELISMOS HOSPITAL, ATHENS.

ENDARTERITIS obliterans of the extremities is nowadays found much more frequently than it was some years ago, because we are more on the look out for this disease, for which a precise method of exploration, based on the oscillometric examination, has been introduced. The frequency of the occurrence of this morbid condition raises important problems as to its physio-pathology and its treatment.

ETIOLOGY.

Following the modern conceptions of general pathology, endarteritis obliterans must be considered essentially a disease of metabolism. A series of external "causes," acting on an individual specially predisposed on account of deficiencies of his regulators of metabolism, determine metabolic disturbances bearing principally on the lipoid metabolism—disturbances which, aided by certain localizing factors, result in the proliferation of the intima of the arteries of the extremities. In the etiology of endarteritis obliterans we have therefore to consider, not a unique cause, but a "constellation"* of external, constitutional, and localizing factors. The most important external evictors are tobacco intoxication, infection, and emotional shocks. The internal or constitutional factors are more as important, and consist in constitutional inadequacies of certain "regulators of metabolism"—namely, of the pancreas, of the adrenals, and of the sympathetic nervous system—inadequacies which are found in certain families with a peculiar frequency, as, for example, in Polish Jews. The factors participating determine the localization of the metabolic disturbances at the apex is on the arterial wall consist in infection of the means of the arterial wall (from typhus, typhoid fever, syphilis, and perhaps from focal infection), and in constitutional metabolic deficiencies of the arterial wall, the arterial hypoesthesias described by F. Parkes Weber.

It must be realized that the constellation of etiological factors can be described only in a general outline. Each individual patient has his own "structure" of constellation—that is, there are individual differences as to the proportionate importance and the mode of combination of the various factors constituting the etiological constellation.

Physio-pathological and Clinical Evolution of Endarteritis Obliterans.

Three phases or periods must be distinguished in the physio-pathological and clinical evolution of endarteritis obliterans of the extremities—a pre-arteritic phase of metabolic disturbances, a phase of incompletely obliterating arteritis, and a phase of thrombo-arteritis.

The Pre-arteritic Phase.—The features of the pre-arteritic phase can only be inferred by considering the metabolic disturbances which have been found in confirmed endarteritis, and which probably precede for many years the endarteritic localization. These disturbances bear on the lipoid metabolism, as can be demonstrated by the occurrence of hypercholesterinaemia (J. Heitz) and the presence of cholesterol deposits in the endarteritic lesions. They are due to disturbed function of the pancreas, adrenals, and sympathetic system. The frequency of endarteritis obliterans in diabetes, and the results obtained by Vaquez and Yacoel with insulin in non-diabetic patients suffering from endarteritis obliterans, show the role of the pancreas, and the results of unilateral adrenalectomy in certain cases (Stulz and Stricker) allow us to admit the role of the adrenals.

The Period of Incompletely Obliterating Arteritis.—After a long period of purely metabolic disturbances the endarteritic lesion occurs, a lesion which is principally trophic—metabolic—although its localization may be aided by infection. The initial and principal phenomenon in this endarteritis consists in the proliferation of the intima—that is, in the multiplication and stratification of the cells of this arterial coat—and, more than that, in the neoformation of connective tissue rich in cells. The lamina elastica interna is often divided; cholesterol deposits are frequent in the proliferating intima; calcium deposits are more tardive, and much less frequent. The involvement of the other coats of the artery is tardive, inconstant, and atypical. The proliferation of the intima causes a narrowing of the arterial lumen, and therefore a diminished irrigation of the limbs. In periods of rest or quiet movements this diminished irrigation is sufficient, but where there is a greater demand for blood, as in more active movements, the incompletely obliterated artery, instead of dilating as it normally does to increase the circulation, contracts spasmodically, and this vascular spasm is felt as pain of "intermittent claudication." Thus the symptoms manifested in this period do not depend on the arterial stenosis, but principally on the adjunction of an abnormal vascular reflex.

The Thrombo-arteritic and Thrombo-angiitic Phase.—This is the terminal phase of endarteritis obliterans, and may occur, as in young individuals, very early. Thrombosis adds itself to the clinical and pathological picture, and dominates it. This thrombosis may begin in a small artery, and extend much further upwards; it may occur also in the satellite veins, this being explained either by a concomitant phlebitis, or by the secondary disturbances of the venous outflow due to the insufficiency of the *vis a tergo*. In this thrombo-arteritic or thrombo-angiitic period of endarteritis obliterans collateral anastomoses develop to relieve the arterial obstruction.

The Place of Endarteritis Obliterans in Nosography.

Endarteritis obliterans is a special localization of athero-sclerosis. In fact, in athero-sclerosis the same constellation of etiological factors, and the same physio-pathological conditions (proliferation of the intima, disturbances in cholesterol metabolism, etc.), are found; and, on the other hand, there are cases which I described as polyarterial syndromes, in which endarteritis of the extremities coincides or alternates with coronaritis, and with endarteritis of the mesenteric arteries. The clinical and physio-pathological history of endarteritis obliterans is identical with that of the other localizations of athero-sclerosis. In

* For nearly all morbid conditions, not only for endarteritis obliterans, we no longer look for "one cause," but for multiple etiological conditions—that is, for a constellation of etiological factors, to use the happy expression of Tendeloo.

athero-sclerotic coronaritis there is first a phase of metabolic troubles, then comes the endarterial localization with vasomotor disturbances, manifested clinically as angina pectoris, and later a thrombosis may occur, resulting in myocardial infarct. In athero-sclerosis of the mesenteric arteries there occurs also, after the prodromic obscure phase of metabolic troubles, the phase of incompletely obliterating endarteritis with vasomotor disturbances manifested by attacks of abdominal pain and constipation, and the terminal phase of thrombo-arteritis with intestinal infarct. The terms used point to that identity. Angina pectoris is often called intermittent claudication of the heart; the pain in mesenteric endarteritis is often described as abdominal angina, or as "dysbasia angio-sclerotica abdominalis" (Ortner). It would be well never to use these terms in clinical diagnosis, as they are liable to bring confusion, but to hold to the precise anatomical diagnosis of the syndrome—coronaritis, mesenteric arteritis, endarteritis obliterans of the extremities.

Thrombo-angiitis obliterans, or Buerger's disease, must not be considered as a special disease differing from endarteritis obliterans. The special etiological features, such as occurrence in young men, predominance in Polish Jews, are not sufficient to justify this absolute separation. Neither are the anatomical features described by Buerger absolutely specific. Arterial thrombosis occurs in endarteritis obliterans. Involvement of the veins with venous thrombosis is also found in endarteritis obliterans of the extremities, and is especially frequent in endarteritis of the mesenteric arteries.

The absence of calcium deposits or of cholesterol deposits in thrombo-angiitis is not absolutely demonstrated, and at all events is not sufficient to separate Buerger's disease from endarteritis obliterans. The giant cells described in the clot are found in all organizing thromboses. The argument put forward by the American authors—namely, that Buerger's disease is due to infection, whereas endarteritis is a trophic disease—is purely theoretical, because the exclusive role of infection in Buerger's disease is only hypothetical, whereas the trophic element is much more apparent. In Buerger's disease the same constellation of etiological factors, the same basic metabolic disturbances, the same clinical evolution, the same action of various therapeutical measures as in endarteritis obliterans, have been described. Endarteritis obliterans and Buerger's disease are therefore one and the same disease, and the most we can say is that on account of a special structure of the etiological constellation (predominance of certain racial constitutional factors) Buerger's disease is a special form of endarteritis obliterans.

Diabetic endarteritis obliterans is also a special form of endarteritis obliterans, and is simply characterized by the preponderance of the pancreatic element in the constellation of etiological factors.

This is the "synthetic" or "metabolic" conception of endarteritis obliterans. It is based on the modern physiopathological researches, is confirmed by the clinical observations of the polyarterial syndromes, and has the merit of offering a sound scientific basis for the treatment of this condition.

Importance of Early Diagnosis for Treatment.

The diagnostic problem is very important, since most cases of endarteritis obliterans are diagnosed as rheumatism, sciatica, varices, flat-foot, etc. These errors will be avoided by bearing in mind the relative frequency of the arterial obstructions of the extremities at all ages and in all countries, and by exploring the circulation of the extremities with the oscillometer. The oscillometric method remains the most simple and the most precise diagnostic procedure, because radiology can give us results only in the rare cases in which calcium deposits exist in the arterial wall, and radiography after injection of *lipiodol* is much more difficult in its application, does not give more precise information than the oscillometer, and is not always innocuous.

In the intensive injection treatment of varices care must be taken not to mistake for real varices the venous dilatations met with in cases of endarteritis obliterans, and which are provoked by the venous stasis frequent in this condition. Injection treatment of such "varicose veins" may lead to disaster, as Sicard himself has pointed out, and this demonstrates the importance, for the internist and the surgeon, of a precise exploration of the arterial circulation of the limbs.

Treatment of the Etiological Factors.

Interdiction of smoking is necessary, and there is always a relief in the symptoms of patients who give up smoking. Syphilis must be looked for, and even, in doubtful cases, treatment with mercury or arsphenamine must be instituted. Active foci of naso-oral infection must be treated in consequence. In a disease which so largely affects the vegetative nervous system the role of careful psychotherapy need hardly be emphasized.

Treatment of the Basic Metabolic Disturbances.

The treatment of the basic metabolic disturbances constitutes the principal element in the treatment of endarteritis obliterans, and, provided an early diagnosis is made through the oscillometric exploration, gives striking results.

The most important method consists in the use of pancreatic preparations directed against the pancreatic element. Vaquez and Yacoel have shown the remarkable results of insulin treatment, and Dr. Quiserne of Bagnolles has made extensive use of pancreatic preparations in peripheral vascular diseases with very encouraging results.* Recent researches of Gley and Kisthinios have demonstrated in the pancreas a special substance, independent of insulin, but existing in insulin as an "impurity," and which has a definite vascular action.

Various protein shock preparations must be used after treatment with insulin has been tried. During these last four years I have used yatren casein, which I prefer to the intravenous administration of T.A.B., advocated by Goodman and Gottesman—a method which may result in strong reactions. Lipiodol, which, on the advice of Professor Vaquez, I have used for many years, acts probably through the same mechanism of shock. There is, however, a special action of the iodine on the metabolic disturbances of the arteries, and that is why preparations such as lipiodol, tincture of iodine, and colloidal iodine are valuable as alternative methods.

Spas, the great modifiers of metabolism, show their action in endarteritis obliterans. I have seen remarkable results from Royat treatment, and although this spa acts principally on the vasomotor element, we cannot exclude a more general regularization of metabolism.

Adrenalectomy belongs also to these metabolic treatments. I have no personal experience of the effect of this method, but I cannot consider the published results as very encouraging.

The methods advocated—insulin, protein shock, lipiodol, spa treatment—very frequently bring about a striking amelioration of the subjective symptoms, and, what perhaps emphasizes their efficiency, an increase of the oscillometric index.

Treatment of the Circulatory Disturbances.

The second objective of the clinician in endarteritis obliterans consists in the diminution of the vascular spasm and the fostering of vaso-dilatation of the vessels of the limbs, so as to bring about as normal an arterial irrigation as possible. The effects of the various methods advocated, which will be used alternatively, must be followed with the oscillometer.

Among the pharmaceutical agents, the nitrites, aspirin, and acetylcholin will yield good results. Nitrites may be given either by the mouth or in the form of injections of sodium nitrite (twenty 1 c.cm. injections of a solution containing 0.01 sodium nitrite per c.cm.). Aspirin, although a banal drug, has real therapeutical effects, as Erb has shown, which are due to the central vaso-dilatory action of the salicylates (Wiechowski). Acetylcholin—in series of daily injections of 0.05 or 0.10—has been introduced in the treatment of this condition by Professor Villaret, and the reports of the French clinicians are very encouraging. Quinine also is used by certain physicians.

* Oral communication.

Among the physio-therapeutical methods, the simplest consists in the application of warm foot-baths, or radiant heat, but the best is diathermy (A. Wilson Gill, L. Newell Moss), which must always be applied. I have not seen any special results from *x*-ray applications, nor from galvanic foot-baths. Massage is strictly contraindicated, as also is any undue strain (exercise), because these can only accentuate the spasmodic condition. Balneotherapy is very important, and it is to the action on the vasomotor centres that must be attributed, in great part at least, the effects of Royat. Artificial carbon dioxide baths are not effective.

Among surgical methods Leriche's operation—arterial perisympathectomy—which also enhances vaso-dilatation, has given some good results, but must be applied only in the last resort. Before its application a careful oscillometric exploration must be made, so as to determine that the artery is not completely obliterated, and also for the localization of the obliteration. Gangrene may be the result if these precautions are not taken.

If to all these methods is added the scrupulous care of small wounds and excoriations of the lower limbs, a very effective treatment can be instituted in a disease which is relatively frequent, is met with in all countries and in all races, and has not, thanks to the possibility of an early recognition, the dark prognosis which was often attached to it.

PERNICIOUS ANAEMIA.

PRELIMINARY REPORT ON THE RESULTS OBTAINED BY TREATMENT WITH CERTAIN PREPARATIONS OF STOMACH.*

BY

JOHN F. WILKINSON, M.B., M.Sc., PH.D., F.I.C.,

DIRECTOR OF THE LABORATORY FOR CLINICAL INVESTIGATIONS AND RESEARCH, MANCHESTER ROYAL INFIRMARY.

THE unfailing regularity with which gastric achylia is encountered in pernicious anaemia has often been pointed out. Almost invariably the gastric secretion is deficient in hydrochloric acid and pepsin, even after the use of powerful gastric stimulants; in some hundred cases which I have examined only three exceptions were found.[1] That this achylia is of some significance has been pointed out by Castle,[2] who fed patients suffering from Addisonian anaemia with beef that had been predigested in a normal stomach, or with normal gastric juice *in vitro*, and obtained reticulocyte responses and increased erythrocyte counts comparable with those ordinarily seen after small doses of liver. He failed to obtain any improvement using beef (*a*) alone, (*b*) predigested with hydrochloric acid and commercial pepsin, or (*c*) incubated with 150 grams of mucous membrane of hog's stomach. The negative result in the latter case is somewhat surprising in view of the results described below.

These observations and the success of the liver therapy have suggested the hypothesis that pernicious anaemia might be a deficiency disease in which the gastric juice was unable to elaborate some necessary principle (normally formed in a healthy individual) from the proteins of the food. This substance is present in liver and kidney, as was originally shown by Murphy and Minot, and, in consequence, these organs can be readily administered in the treatment of the disease. Attempts to identify the active principle with certain vitamins and investigations upon the effects of various foodstuffs have been made by Elders,[3] and Koessler, Maurer, and Loughlin[4] among others.

The experiments described below were based upon a somewhat different view—namely, the possibility of pernicious anaemia being a type of deficiency disease, in which some factor of paramount importance was absent from the gastric juice. Despite some of the negative results obtained by Castle, it did not seem improbable that the stomach itself might be a potent source of the anti-anaemic substance, and the complete lack of gastric enzymes suggested the importance of investigating this possibility more closely.

Action of Normal Gastric Juice.

It was decided in the first place to try the effect of normal gastric juice. This was obtained, as required, either with or without the use of histamine, and administered in a daily dose of 150 to 200 c.cm., *given during meals* to ensure its action upon the protein foodstuffs. Each individual sample of gastric juice was examined carefully beforehand for the presence of free hydrochloric acid and normal peptic activity to ensure that an active and fresh preparation was being used. All samples containing bile, or less than 0.036 per cent. free hydrochloric acid, were discarded.

The following case illustrates the type of response obtained in this group.

CASE I.

A male cotton operative, aged 59, was admitted to hospital complaining of weakness in the legs and lack of energy, so that he was unable to carry on his work. Apart from bacterial food poisoning in 1906, he had enjoyed perfect health until March, 1929, when he had an attack of influenza lasting for four weeks. Since that time he had had slight paraesthesias, more pronounced in the cold weather. These became gradually worse, so that, having ceased work, he had difficulty in using his limbs accurately. He had lost 14 lb. in weight in six months. His appetite was good and there was no history of indigestion, diarrhoea, nausea, vomiting, or marked flatulence. He had soreness of the tongue and gums in cold weather. More recently, he had had some slight pains in the lower abdomen, lasting for a few minutes only; his bowels were constipated.

The previous medical history contained nothing of note. As regards the family history, one sister had died at the age of 30 from an "anaemic wasting disease."

Examination.—The patient's teeth were artificial; there was nothing abnormal in the cardio-vascular, respiratory, alimentary, or genito-urinary systems. The knee-jerks and abdominal reflexes were exaggerated; no muscular wasting was present, but there was marked weakness in the limbs and some difficulty in walking. The blood Wassermann test was negative. A cytological examination showed: red blood cells 3,650,000 per c.mm., white blood cells 4,800; haemoglobin 100 per cent.; colour index 1.4; platelets normal; slight anisocytosis and poikilocytosis; no nucleated red cells or abnormal staining detected. Repeated fractional gastric analyses revealed complete achylia.

The case was diagnosed as one of early pernicious anaemia with subacute combined degeneration of the cord and achlorhydria syndrome.

Treatment.—No liver had been taken prior to admission, when he was given hydrochloric acid and commercial pepsin. After seven days this was discontinued and replaced by 150 to 200 c.cm. of normal fresh gastric juice once daily, taken with the midday meal. During the first week, while on acid and pepsin therapy, the patient's condition became worse. The reticulocyte count remained at the normal low level, while the red blood cells diminished by nearly 300,000; anisocytosis and poikilocytosis became

* From the Laboratory for Clinical Investigations and Research, Manchester Royal Infirmary

marked, and the platelets were reduced in numbers considerably. The introduction of normal gastric juice, however, gave a remarkable response. Within three or four days the reticulocytes showed an increase (Chart 1) somewhat greater than that obtained with liver in similar cases. (It should be noted that Minot, Murphy, and Stetson[5] have shown that the height to which the percentage of reticulocytes rises in the usual case is in inverse relation to the level of the red blood cells. Cases with more than three million red blood cells per cubic centimetre never exhibit more than a slight response (about 1 per cent.) of the reticulocytes.) Simultaneously the red blood cells showed an increase in numbers to over four million. The patient was obviously much better and felt stronger, so that he was able to walk and use his hands and arms almost as normally. He had now improved so considerably that he asked to be discharged from hospital, and liver extract was substituted in place of the normal gastric juice for several days, the reticulocyte percentage falling immediately without any secondary rise, a significant point in the diagnosis and treatment of this condition. He was discharged on a liver diet.

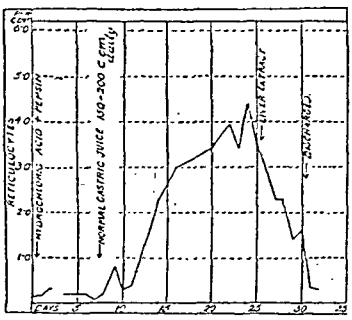

CHART 1.

Uncooked Fresh Hog's Stomach.

Freshly obtained hogs' stomachs were employed in the next group of cases. In order to differentiate, if possible, between the value of the mucous membrane and the muscular layer of the stomach, these were separated. This was readily accomplished by stripping and slight dissection. In this manner the two portions were obtained free from each other, weighed, minced, and fed to patients suffering from pernicious anaemia. One stomach daily was thus sufficient for the treatment of two patients. It was found subsequently that the two portions were equally potent, even when kept in a refrigerator for several days—an important practical point in treatment extending over periods of weeks or months.

It may be pointed out that the separation of the two portions of the fresh stomach as received each day successfully disposes of the argument that the potency of the stomach muscle, at any rate, is due to the action of pepsin present in the stomach post mortem.

The minced daily doses were readily administered to the patients in the usual ways as employed with fresh liver therapy, no cooking or heating being permitted (compare Wilkinson and Brockbank, loc. cit.). No hydrochloric acid or other drugs were administered during the periods of observation. The following cases illustrate the typical results obtained.

CASE II.

A woman, aged 41, who was engaged in housework, had complained of lassitude and loss of energy since 1922. She improved for a time, and then attacks of nausea, persistent vomiting, and some diarrhoea began, lasting for periods of about a week. This continued, with some intervals of freedom, from 1925 until the spring of 1929, when an appendicectomy was performed. From this time onwards she became progressively weaker and more anaemic. She had neither nausea nor diarrhoea until the day of admission to hospital, but gave a history of occasional indigestion, soreness of the tongue, and slight oedema of the ankles. There was no definite flatulence or loss of weight.

The previous medical history contained a reference to an attack of bacterial food poisoning in 1914. As regards the family history, the father died of phthisis, and the mother has a weak chest.

Examination.—The teeth were carious; the tongue was pale, but there was no marked glossitis; the skin had a pale yellowish tinge. The spleen was slightly enlarged; there was a systolic bruit over the pulmonary area, but nothing else of note was observed. A blood count showed: red blood cells 660,000 per c.mm., white blood cells 3,200; haemoglobin 17 per cent.; colour index 1.3; platelets scanty; anisocytosis and poikilocytosis marked; nucleated red cells, polychromasia, punctate basophilia, and megaloblasts all present. Fractional gastric analysis showed achylia gastrica.

This patient had not had any liver therapy prior to admission. A blood transfusion (Group IV, 350 c.cm. whole blood by the direct method) was given, followed by a daily dose of 250 grams of freshly prepared raw mucous membrane of hog's stomach. The patient was troubled from the day of admission with severe diarrhoea, which commenced before the raw stomach therapy had been inaugurated, persisted for four or five days, and responded to large doses of hydrochloric acid.

The reticulocytes began to show a rapid response, increasing in numbers. Simultaneously, the subjective and objective conditions of the patient improved progressively and rapidly. Further supplies of desiccated mucous membrane being now available (see below), 100 grams daily was substituted for the raw preparation (Chart 2). It will be observed that after the first peak had been reached the percentage of reticulocytes fell to below 5 per cent. and then gave a secondary rise in the course of some five days to 10.6 per cent. The significance of this is not quite clear, and, so far in my series, this is the only example. The erythrocytes showed a steadily increasing count, rising from 660,000 per c.mm. before transfusion to 1,022,000 two days later, and 3,910,000 after fifty days.

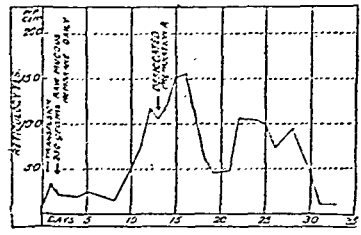

CHART 2.

CASE III.

A male clerk, aged 56, complained of weakness, lack of energy, pallor, and tingling and numbness in the fingers and toes, so that he was unable to follow his employment. The onset had been insidious, but had become more pronounced during the three months prior to admission to hospital. With the onset of constipation and the passage of frequent small motions he had noticed a change of colour of his skin, and developed a very marked heaviness about the eyes. There was no history of flatulence, indigestion, diarrhoea, or soreness of the tongue. Thirty-four years previously he had had jaundice, which lasted for six to seven weeks; he was in hospital twenty years later on account of abdominal pain; no operation was performed.

The family history showed that several members of the family had had jaundice; a cousin died of gastric cancer; his mother was troubled with indigestion for years.

Examination.—The teeth were artificial; the skin a lemon-yellow colour; there was impairment of muscular power in the upper and lower limbs, and evidence of chronic bronchitis; nothing else of note. A blood count showed: red blood cells 1,910,000 per c.mm., white blood cells 7,600; haemoglobin 50 per cent.; colour index 1.3; platelets scanty; anisocytosis and poikilocytosis marked; nucleated red cells, polychromasia, and megaloblasts present. Fractional gastric analyses on several occasions showed complete achylia.

Prior to admission this patient had taken small doses of cooked liver at irregular intervals. As in the previous case, he was given a diet containing 250 grams of fresh raw mucous membrane daily. Again the improvement in the patient's general condition was profound, so that he was able to attend the laboratory without assistance in less than a week.

Table (abridged) showing Improvement in the Blood Count.

Day of Treatment.	Red Blood Cells.	White Blood Cells.	Haemoglobin.
			Per cent.
First day	1,910,000	7,600	50
Twenty-first day	2,820,000	6,400	60
Thirty-sixth day	3,740,000	14,100	74
Fifty-fourth day	4,390,000	13,200	72
Sixty-eighth day	4,570,000	11,100	74
Seventy-eighth day	5,072,000	8,300	84

The blood picture showed similar improvement (see table), to such an extent that, having continued the dietary after discharge from hospital, his erythrocyte count had increased from 1,910,000 to 5,072,000 per c.mm. in nine weeks *from the commencement of fresh stomach therapy.* He is now very well indeed, *having returned to work with an almost normal blood picture* within two and a half months from the original diagnosis of the condition. This compares very favourably indeed with the results obtained on a liver diet.

CASE IV.

A foreman gasworker, aged 36, was admitted to hospital complaining of progressive loss of energy, dyspnoea, and general weakness for three months prior to admission, becoming very marked during the latter portion of this time, when a yellowish pallor was also observed. In January, 1929, he had been operated

upon in another part of the country for appendicitis, since when he had had occasional slight discomfort after food and exertion. There was no history of soreness of the tongue, nausea, vomiting, flatulence, diarrhoea, or loss of weight. Slight paraesthesiae were present in the toes. There was nothing of note in previous medical and family histories.

Examination.—A slight yellowish pallor of the skin was noticed; nothing else abnormal was found. A blood count showed: red blood cells 3,180,000 per c.mm., white blood cells 5,200; haemoglobin 66 per cent.; colour index 1.04; platelets scanty; anisocytosis and poikilocytosis marked; no nucleated red cells; no abnormal staining. Fractional gastric analyses on four separate occasions showed achylia.

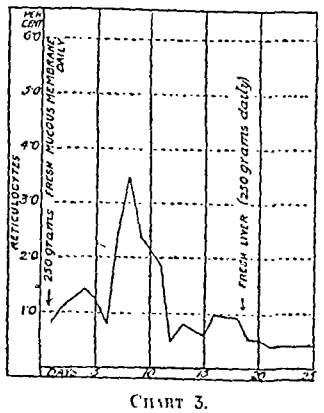

CHART 3.

The diagnosis was obviously one of pernicious anaemia. Prior to admission the patient had taken small amounts of cooked liver for some seven days, but no treatment was given for a week preceding the administration of fresh stomach muscle (250 grams daily). This, of course, does not entirely preclude the possibility that the earlier liver treatment may have initiated a remission. However, the response of the reticulocytes (Chart 3) to the stomach therapy is significant, following as it does a preliminary liver diet (compare Minot, Murphy, and Lawson[6]).

Here again, as in Case i, the prompt response was quite equal to that obtainable with liver therapy in cases showing an initial red cell count greater than three million (loc. cit.). No further response was obtainable with a liver diet subsequently. The patient showed a very marked improvement in his condition, and his paraesthesiae disappeared entirely on the raw stomach diet.

This case is included here in order to illustrate the type of response that is usually observed in cases with an initial high red blood cell count. It is typical for both stomach and liver therapy.

Desiccated Preparations of Hogs' Stomachs.

The obvious difficulties attending the supply and use of fresh raw hog's stomach after the patients have left hospital suggested the substitution of the corresponding dried preparations. Whilst these experiments were in progress Sturgis, Isaacs, and Sharp[7] reported the treatment with desiccated whole stomach of three cases, which showed very similar results to my own.

I employed dried mucous membrane and dried muscular layer of hogs' stomachs in cases as described below. The preparations were obtained by desiccation at 40° C. *in vacuo*, with the addition of lactose to facilitate manipulation. Thus obtained, both portions of the stomach were in the form of light powders, which were readily administered in the following ways: (*a*) suspended in water or milk; (*b*) in lukewarm soup, etc.; (*c*) mixed with other previously cooked foods, particularly potted meat, in which guise the patient was unable to detect its presence; and (*d*) in the form of tablets to be swallowed with water or other fluid at intervals during the day. Later preparations were flavoured with chocolate and made a very palatable drink with milk. As employed at the present time these two preparations are:

Preparation A.—The usual dose of 100 grams contains 66 grams of desiccated mucous membrane of the hog's stomach, equivalent to about 280 grams of fresh mucous membrane. The remainder consists of chocolate and lactose.

Preparation B.—The usual doses employed were 150 grams, and later 100 grams. The former dose contains 100 grams of desiccated stomach muscle (equivalent to 300 grams of the fresh product), the remainder consisting of added chocolate and lactose.

The bulk of both these preparations can be considerably reduced by omitting the chocolate and lactose, but this is of little advantage in practice.

The following cases are typical examples from my series.

CASE V.

The illness in this patient—a woman teacher, aged 47—commenced in May, 1926, with soreness of the tongue and mouth, which continued with remissions for fourteen months. From this time onwards she was troubled with weakness and lack of energy to such an extent that most of her week-ends were spent in bed, although she managed to remain at her work. In April, 1929, she had an attack of jaundice which lasted for five weeks, although the yellowish colour had never been completely lost. She had had tinglings and numbness in the hands and feet for several years, together with some indigestion and flatulence, and in the summer of 1929 complained of pain in the chest and both iliac fossae. The bowels had been constipated, and vomiting had occurred at irregular intervals after food. She had suffered from cystitis and pyelitis in 1927. There was nothing of note in the family history.

Examination.—Her tongue was clean, no evidence of glossitis; teeth good; skin lemon yellow colour; nothing else found abnormal.

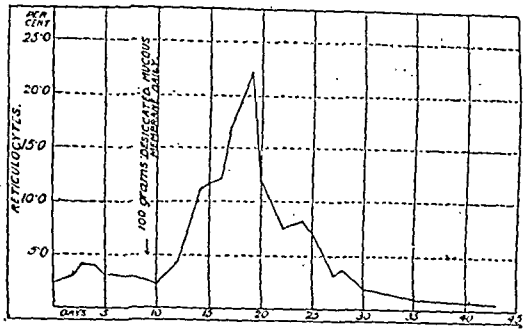

CHART 4.

Van den Bergh reaction: delayed direct. Radiological examinations of alimentary tract and gall-bladder were negative. A blood count showed: red blood cells 1,890,000 per c.mm., white blood cells 5,300; haemoglobin 55 per cent.; colour index 1.45; platelets very scanty; anisocytosis and poikilocytosis very marked; no nucleated red cells. Fractional gastric analyses showed complete achylia.

This patient was sent into hospital as a case of cholelithiasis, but the diagnosis was obviously one of pernicious anaemia. She had not had any liver therapy.

For the first ten days she was given hydrochloric acid and pepsin with each meal without response. This was then amplified by the addition of 110 grams of desiccated mucous membrane (preparation A) of hog's stomach daily, but was later reduced to 100 grams daily. Chart 4 shows the almost immediate response in the reticulocyte percentage, and the progressive rise in the erythrocyte count. There was no secondary rise in the curve after it had fallen to normal (less than 1 per cent.), where it remained subsequently. The clinical condition began to show an extremely rapid rate of improvement, the paraesthesiae and icteric colour having completely disappeared within a week after the commencement of the treatment.

After thirty-five days the patient had shown an increase from 1,890,000 to 4,136,000 erythrocytes per cubic millimetre, and was discharged from hospital.

CASE VI.

An engineer's fitter, aged 45, complained of excessive tiredness after work or exercise, together with a feeling of "being run down" during the six weeks prior to admission to hospital. Since that time he had become progressively worse, and had noticed that he was getting paler in colour and very anaemic. There was dyspnoea on slight exertion, and a history of swelling of the feet and ankles, and much indigestion. There had not been any cough, pain, loss of weight, nausea, vomiting, diarrhoea, or paraesthesia. His bowels were regular. His previous medical and family histories contained nothing of note.

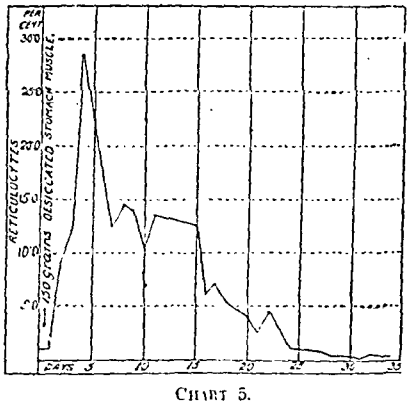

CHART 5.

Examination.—He had pale yellow sclerotics, with faint yellow colour in the skin; teeth artificial; tongue clean, dry; no oedema; liver enlarged; spleen just palpable; nothing else abnormal. The blood Wassermann test was negative. Radiological examination of the alimentary tract was negative. A blood count showed: red blood cells 1,224,000 per c.mm., white blood cells 6,100; haemoglobin 45 per cent.; colour index 1.8; platelets very scanty; anisocytosis and poikilocytosis very marked; nucleated red cells, megaloblasts, polychromasia, and punctate basophilia all present. Fractional gastric analyses showed complete achylia.

The patient was treated with desiccated stomach muscle (preparation B), initially 150 grams daily, with a rapid response in both erythrocyte and reticulocyte counts. The reticulocytes (Chart 5) rapidly rose to 23.3 per cent., but had not reached a normal level again until the twenty-eighth day after commencement of the treatment, when the dosage was reduced to 100 grams daily. The red blood cells rose steadily and progressively until their count was 4,008,000 per c.mm. on the thirty-seventh day, when the patient was discharged from hospital.

Summary.

The present communication is a summary of the results obtained in a preliminary series of nine cases of pernicious anaemia. These were divided into three groups, which were treated respectively with (*a*) normal gastric juice, (*b*) raw fresh mucous membrane or muscular layer of hogs' stomachs, and (*c*) desiccated preparations from these two portions of the stomach of the hog.

The results were controlled by daily reticulocyte counts, frequent regular full blood examinations, and the clinical conditions of the patients, both before and after discharge from hospital.

Cases of pernicious anaemia in various stages of the disease have been examined, and the final results obtained in all cases are at least equal to, whilst the immediate clinical results appear to be distinctly better than, those obtained in corresponding cases on a fresh liver diet.

Representative cases from each group under observation have been described to illustrate points brought out in the present communication.

It is not proposed to discuss here the theoretical considerations raised until the series has been extended more fully. Briefly, however, the results are these:

1. Normal gastric juice (150–200 c.cm. daily *with* meals) has given a definite improvement in the clinical condition, blood picture, and reticulocyte response slightly better than is observed with a fresh liver diet under similar conditions. This tends to support some of the observations made by Castle.

2. Hydrochloric acid and commercial pepsin alone have no effect in the improvement of the haematological condition of pernicious anaemia, nor are they essential for successful treatment with stomach of the hog.

3. The mucous membrane and the muscular layer of the stomach of the hog are both active in the treatment of pernicious anaemia. The results so far obtained show that this diet, weight for weight, is at least equal to or better than a liver diet.

4. Similarly, desiccated preparations of these two separated portions of hog's stomach are potent in the successful treatment of the disease. This form is convenient and easy to administer.

5. Clinically there is little difference in the potencies of all the preparations of hog's stomach described above, whilst fresh stomachs, both whole and dissected, have been kept for several days at a low temperature without noticeable loss in activity.

6. Compared to liver, the results appear to be slightly better, and the improvement in the condition of the patients in my short preliminary series has certainly been more rapid with hog's stomach therapy. Glossitis and paraesthesiae, in particular, have been found to respond more readily.

7. Since both the peptic-enzyme-containing (mucous membrane) and the non-peptic-enzyme-containing (muscle) portions of the stomach of the hog are active, they may be placed in the same category as liver and kidney as very potent sources of the active haematopoietic substance.

8. Eosinophilia occurs with this form of therapy as with liver.

It is proposed to give fuller details at a later date of these investigations, together with certain other work now in progress, when the series will have been much extended.

I have again to thank the honorary physicians of the Manchester Royal Infirmary for kindly allowing me to use their patients in this investigation, Professor H. S. Raper, F.R.S., for his unfailing interest and help, and Drs. Agnes Bodoano and Bessie Cadness for their careful determinations of the reticulocyte and blood counts. I gratefully acknowledge, also, the invaluable assistance rendered by Messrs. Benger's Food, Ltd., of Manchester, and Dr. Bullock, who kindly went to considerable trouble to prepare for me the desiccated preparations from the fresh hogs' stomachs.

THE INJECTION CURE OF HYDROCELE.

BY

F. C. PYBUS, M.S., F.R.C.S.,

SURGEON, ROYAL VICTORIA INFIRMARY, NEWCASTLE-UPON-TYNE.

IT must be presumed that the old procedure of injection for the cure of hydrocele of the tunica vaginalis was unsatisfactory, either because of the uncertainty of its results or on account of its painful character, and it fell into disuse. The substitution of operative measures, while satisfactory in their respective technique and results, was a somewhat severe procedure for old patients. The use of general anaesthesia, the stay in bed for some ten days or longer, and the difficulty in finding hospital accommodation for such cases, made the need for a simpler procedure desirable.

The risk of general anaesthesia might be obviated by the substitution of local, which was entirely satisfactory, but the period of convalescence was not abolished. An extended use of quinine and urethane for the injection of varicose veins suggested that one had a solution which might serve an equally useful purpose to damage the endothelium of the tunica, and that with a minimum of pain and reaction.

The method was first tried in June, 1928, at the Royal Victoria Infirmary, on a patient aged 54, who had had a right hydrocele for two years, during which time it had been tapped ten times. It regularly filled up in two months. A small area of the front of the scrotum was infiltrated with novocain, and the tunica tapped by the ordinary hydrocele trocar. As far as possible the tunica was emptied and 2 c.cm. of quinine and urethane introduced through a spinal anaesthetic needle passed through the cannula. The needle was withdrawn, and later the cannula, care being taken to avoid any contact between the solution and the other tissues. By gentle massage the solution was distributed over the whole surface of the tunica. Fluid gradually re-accumulated and was aspirated seven days later, and was found to be slightly turbid. No pain, discomfort, oedema, or fever was manifested, and the patient was then discharged. At the present time, eighteen months later, there has been no return of the fluid.

Shortly after, a second case, a patient aged 72, in whom the hydrocele had been present for some years and who had been tapped several months before, presented himself with the tunica again very tense and about the size of a coco-nut. A similar procedure was carried out, except that the hydrocele was aspirated through a spinal anaesthetic needle and injected through the needle without withdrawal—that is, by means of a single puncture. No pain was experienced. Fluid again accumulated and was aspirated a week later, it being slightly turbid as in the first case. At the present time there has been no return of the fluid; the testicle is slightly thickened, but a suspensory bandage previously worn has been discarded.

The first patient was admitted to hospital as a precaution, but all others have been dealt with as out-patients, and the treatment in no way interfered with their ordinary duties.

Since then three further patients have been treated, over a year ago, with correspondingly satisfactory results; although tapping was practised after operation in these cases, further experience may prove that this is unnecessary, the fluid being gradually absorbed.

It appears that we have now a satisfactory injection treatment for hydrocele, which is painless and, like the similar method in use for varicose veins, can be carried out without invalidity.

A STUDY OF CUTANEOUS SENSITIVENESS TO SCARLATINAL TOXIN IN PREGNANCY AND THE PUERPERIUM.

BY

HAROLD BURT-WHITE, M.D.LOND., F.R.C.S.ENG.,
ASSISTANT SURGEON, CITY OF LONDON MATERNITY HOSPITAL; CHIEF ASSISTANT TO THE OBSTETRICAL DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL;

LEONARD COLEBROOK, M.B., B.S.LOND.,
ASSISTANT TO THE BACTERIOLOGICAL DEPARTMENT, MEDICAL RESEARCH COUNCIL;

GERTRUDE MORGAN, M.B., B.CHIR.CANTAB.; BEATRICE J. W. JERVIS, M.B., B.S.LOND.;

AND

GERTRUDE E. HARRE, M.B., B.S.LOND., D.P.H.

THIS paper is primarily concerned with the relation between cutaneous sensitiveness to streptococcal toxin in pregnant women and the incidence of puerperal sepsis.

The work was undertaken at the suggestion of the Streptococcal Committee of the Medical Research Council following the report of a hundred cases similarly investigated by one of us (H. B.-W.). The relationship between a positive Dick test and susceptibility to scarlet fever is now well appreciated. The close relationship between haemolytic streptococci isolated from cases of puerperal sepsis and of scarlet fever suggested that the incidence of streptococcal puerperal infection might be governed to some extent by a similar condition of sensitiveness to streptococcal toxins.

Kunz and Nobel published in 1926 the results of Dick tests carried out on 117 women before labour, and 327 within forty-eight hours of delivery. Of these 444 women, 392 (88 per cent.) gave negative reactions, and 52 (12 per cent.) positive. In the Dick-negative group 32 (8 per cent.), and in the Dick-positive group 12 (23 per cent.), experienced febrile puerperia. The febrile standard was not defined, but cases were excluded which showed a rise of temperature on one day only.

Weiss, in 1927, recorded the results of 140 Dick tests carried out during pregnancy. Of the Dick-negative women 34 per cent., and of the Dick-positive 22 per cent., were febrile during the puerperium. The febrile standard was not defined. He was of the opinion that the results were of little value, because in many cases the skin reactions were inconstant. In neither of these investigations, nor in that of Salmond and Turner, were bacteriological examinations carried out to determine specifically the incidence of *S. pyogenes* infection. It was felt that to make the investigation complete such a bacteriological examination should be made.

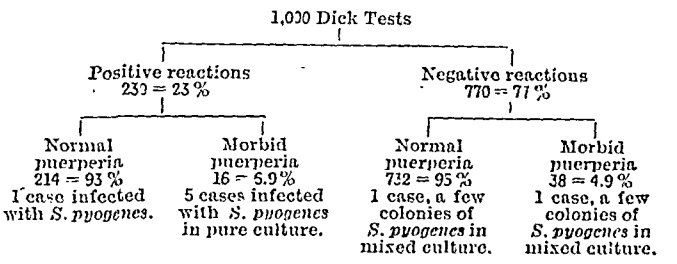
Method.

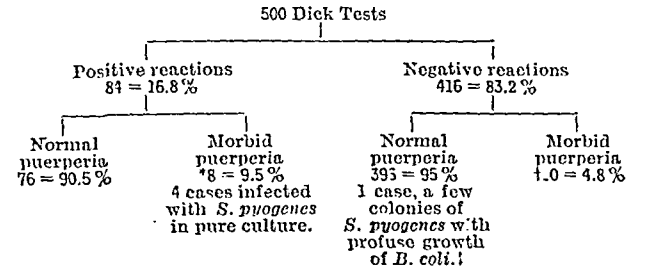
The Dick test was employed. A supply of standardized scarlatinal toxin prepared at the Wellcome Physiological Research Institute has been used for all tests. The Dick toxin was a filtrate of the Dochez strain grown in nutrient broth for eighteen hours at 37° C. No serum or blood had been added. The filtrate gave reactions in very sensitive people in a dilution of 1 in 6,000 and even lower, the dose used being always 0.2 c.cm. Various dilutions had been tested clinically in a number of patients suffering from scarlet fever over a long period. 1 in 1,000 was considered on the clinical results to be the most suitable dilution. Two intradermal injections—one of 0.2 c.cm. of a dilution of 1 in 1,000 of toxin, the other of heated control—were made into the skin of the ventral surface of the forearm, different arms being used for toxin and control. A positive reaction consists in the appearance within twenty-four hours of an erythematous patch measuring at least 1 cm. by 1 cm. at the site of injection, all lesser reactions being regarded as negative. In the majority of cases the test was carried out during the last four weeks of pregnancy. All cases were delivered in hospital; cases in which the reactions were ambiguous have been excluded, so that a high standard of accuracy is assured in the observations. This communication comprises the results of two separate and independent inquiries, conducted simultaneously, at the City of London Maternity Hospital and Queen Charlotte's Hospital. The purpose of the two inquiries was identical, the results are in harmony and have therefore been published jointly. In all cases with morbid puerperia cultures were taken from the cervix whenever possible. The cervical swabs taken at Queen Charlotte's Hospital were plated out on blood agar plates; those taken at the City of London Maternity Hospital were treated by two methods: (1) the swabs were plated out on blood agar plates, and (2) were shaken up in blood broth, which was incubated for eighteen hours and then plated out on blood agar. The standard of morbidity employed was that of a rise of temperature to 100.4° F. or over, maintained for twenty-four hours, or recurring on two occasions within twenty-four hours during the first twenty-one days of the puerperium.

Results.

It has been thought best to show the main results in three tables. Table I is a summary of the 1,000 cases considered as a whole. Tables II and III represent the cases at the City of London Maternity Hospital and Queen Charlotte's Hospital taken separately.

TABLE I.—*Total results of 1,000 Cases at the City of London Maternity Hospital and Queen Charlotte's Hospital.*





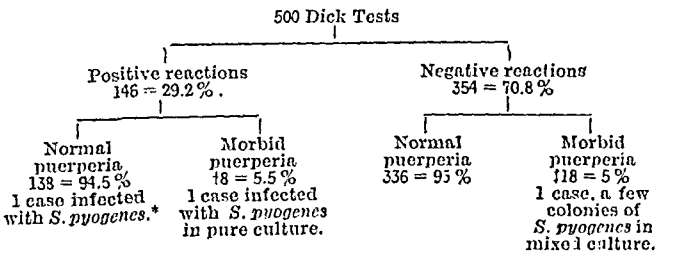


TABLE II.—*The City of London Maternity Hospital.*

* Includes 1 case of breast abscess from which *S. pyogenes* was isolated.
† Includes 3 cases of urinary infection, and 1 case of mastitis.
‡ Pyrexia just short of the morbid standard.

TABLE III.—*Queen Charlotte's Hospital.*

* This case just failed to reach the standard of morbidity. The patient's temperature was on one occasion 100.8° F., and remained for a few hours at 100° F.
† Includes one case of breast abscess.
‡ Includes three cases in which the fever was probably due to infection of the respiratory rather than the genital tract.

The results show that in a series of 230 women giving positive Dick reactions in pregnancy 16 (6.9 per cent.) experienced morbid puerperia, and in 5 cases a pure growth of *S. pyogenes* was isolated from the cervix; in one other case a pure growth of *S. pyogenes* was isolated from a breast abscess. In the Dick-negative group there were 770 women, and of these 38 (4.9 per cent.) experienced morbid puerperia. In this Dick-negative group, over three

times larger than the Dick-positive, 2 cases showed a few colonies of *S. pyogenes* in mixed culture. Considered purely from the point of view of the incidence of *S. pyogenes* infection the results are as follows:

In the Dick + group of women, 6 cases out of 230 = 2.6%
In the Dick − group of women, 2 cases out of 770 = 0.26%

Supplementary Investigations.

1. The Dick test was applied to 38 women at Queen Charlotte's Hospital during the puerperium—that is, either shortly after delivery or within twenty-four to thirty-six hours after the onset of fever. These were cases not included in the larger investigation. Since many of them were already febrile when the Dick test was carried out, the incidence of "morbidity" in the positive and negative groups is of no significance. Of the 38 cases, 8 gave a positive Dick reaction, and of these 5 were "morbid." Bacteriological investigation of these morbid cases showed only one infection (that is, 1 in 5) by haemolytic streptococci—a case of slight uterine sepsis. Of the 30 cases with a negative Dick reaction, 20 were febrile and were investigated bacteriologically. Three cases (that is, 1 in 6.6) showed infection by haemolytic streptococci—two being mild local infections, and the third a moderately severe case in which the fatal result was due chiefly to secondary haemorrhage.

2. The Dick test was repeated in some 26 cases at Queen Charlotte's Hospital in order to determine whether the skin reaction to streptococcal toxin changed from time to time as claimed by Weiss.

15 cases were tested before labour and once during the puerperium.
4 cases were tested before labour and twice during the puerperium.
7 cases were tested twice during the puerperium.

Ten of the patients tested were Dick-positive, 16 of them Dick-negative. In only one case was there a different reaction on re-testing—a positive before labour changing to a negative after labour in a patient whose puerperium was afebrile.

Conclusions.

1. There is a suggestion that women with positive Dick reactions show an increased susceptibility to puerperal morbidity. In this series the morbidity in the Dick-positive was 41 per cent. greater than in the Dick-negative group.

2. The Dick-negative group was three times as large as the Dick-positive, but the actual number of cases infected with *S. pyogenes* was greater in the positive group.

3. Even if the pure cultures of *S. pyogenes* in the positive group be considered to be on an equal footing with the mixed cultures of *S. pyogenes* occurring in the negative group, the incidence of *S. pyogenes* infection in the puerperium was ten times greater in the Dick-positive group (6 cases out of 230) than in the Dick-negative group (2 cases out of 770).

4. It is suggested that skin sensitiveness to scarlatinal toxin may indicate a special liability to streptococcal infection, but definite conclusions cannot safely be drawn from a series including so small a number of cases of *S. pyogenes* infection. It would have been necessary to extend the inquiry to a group of not less than 10,000 women to obtain anything like conclusive evidence on this point.

5. In view of the comparative rarity of streptococcal infection (0.8 per cent.) which is demonstrated by the present investigation, *there would seem to be no case for* the active immunization of all expectant mothers, nor even of all who are Dick-positive. Until data are available which show more conclusively whether there is a close correlation between Dick-sensitiveness and streptococcal infection in the puerperium, it is suggested that Dick testing should be confined to women who have passed through complicated labours, and that the positive reactors among these might be immunized passively by the injection of streptococcal antitoxic serum.

We wish to express our thanks to the committees of management and the staffs of Queen Charlotte's Hospital and the City of London Maternity Hospital for permission to utilize their cases. Our thanks are also due to the resident medical officers of these hospitals (Drs. R. J. Cox and M. Hoggs of Queen Charlotte's and Mr. E. R. Rees and Mr. J. H. O. Roberts at the City of London Maternity Hospital) for help in the work; and to the Wellcome Physiological Research Laboratory for the generous supply of toxin. All of us, with the exception of one (H. B.-W.) were in receipt of grants from the Medical Research Council.

THE FREQUENCY OF STREPTOCOCCUS PYOGENES INFECTION IN PUERPERAL FEVER.

BY

LEONARD COLEBROOK, M.B., B.S.LOND.,

ASSISTANT TO THE BACTERIOLOGICAL DEPARTMENT, MEDICAL RESEARCH COUNCIL;

AND

RONALD HARE, M.B., B.S.LOND.*

PUBLISHED reports from all over the world have made it clear that the most common infecting agent in severe puerperal fever is *Streptococcus pyogenes*. It has been commonly assumed that this microbe is responsible also for most of the less severe infections of the puerperium. Some recent investigations, however, have thrown doubt upon that assumption. White (1927) in Melbourne found only one *S. pyogenes* infection out of a series of 25 cases of so-called "sapraemia" bacteriologically examined; Lucy Bryce (1928), also in Melbourne, reported 6 cases out of 50; and more recently Armstrong and Burt-White reported 8 such infections in a series of 34 mildly febrile cases.

The Dick test inquiry reported in the preceding article by Burt-White, Colebrook, and others, afforded a suitable opportunity for obtaining further data about the incidence of streptococcal infections. For a period of nine months practically every case at Queen Charlotte's Hospital which developed a temperature of 100° F. or more at any time after the first fifteen hours of the puerperium has been investigated bacteriologically—that is, by culture (on blood agar plates) from the cervix uteri, and in some cases also from the blood and urine. The cases so examined include all those classed as "morbid" in the Dick test inquiry.

S. pyogenes was identified by the following characters: its colonies, after twenty-four hours' incubation on horse or human blood agar (3 to 5 per cent.), were surrounded by a zone of 1 to 2 millimetres in which the red corpuscles were destroyed and the haemoglobin decolorized. (Later this zone increased somewhat in width.) These colonies were always round, slightly convex, semi-transparent at their periphery, becoming rather more opaque at the centre; their surface was usually matt, they did not adhere to the medium, and they were of soft consistency, allowing the platinum loop to sink into them. The stained cocci from such surface colonies were round. In a word, they correspond to the beta type of Brown (1919). The total figures obtained were as follows:

Deliveries	1,626
Febrile (all grades except those limited to the fifteen hours following labour)	134
Infections by *S. pyogenes*	19

It appears, therefore, that infection by S. pyogenes is a comparatively infrequent cause of the minor febrile disturbances of the puerperium. Much more commonly these were associated with infection by *B. coli*, diphtheroid bacilli (minute colonies on blood agar), non-haemolytic streptococci, and various unclassified Gram-negative organisms. Whether the presence of these organisms indicates actual infection of the tissues or not, has not been determined.

One or two other points of interest may be noted. First, the cases infected with *S. pyogenes* were not all of a clinically severe type. Only one died from secondary

* Working with a part-time grant from the Medical Research Council.

haemorrhage), and only one other gave rise to any anxiety—chiefly on account of her mental condition. This was the only case of septicaemia. The remaining eight cases were all mild infections; two of them were scarcely ill at all. It would seem, therefore, that though the presence of haemolytic streptococci in a culture from the uterus—especially if it is an abundant, nearly pure growth—should be looked upon as a potentially serious matter, it does not necessarily justify a grave prognosis. Secondly, it may be noticed that though strict isolation of the 10 patients who harboured haemolytic streptococci was impossible, the infection was not transferred—except possibly in one instance—to another patient in the hospital.

MEDICAL, SURGICAL, OBSTETRICAL.

GASTROSTAXIS FOLLOWING BURNS.

THE tannic acid treatment of burns and scalds has given us very satisfactory results; of 80 children under 16 years of age admitted for these conditions during 1929 only 6 died, these deaths occurring either in children admitted several days after the accident, or in those treated with oil before admission. Yet recently a child, in spite of early and efficient tannic acid treatment, died on the nineteenth day, although at the time the wounds had almost healed, and we are in doubt as to the precise relation of the injury and of the tannic acid treatment to the fatal result.

K. G., aged 2 years and 10 months, at 11.30 a.m. sustained scalds of the first and second degree on the abdomen, left thigh from groin to knee, and left forearm. Tannic acid spray was used at 2 p.m. with the hot air bath. The coagulum was quite satisfactory. Two days later the child was restless and vomited; on the next day there was considerable thirst, but no vomiting. In a week the thigh crust was separating with slight purulent discharge, and by the end of the second week the coagulum on the abdomen had separated, healing being satisfactory. The thigh showed a small raw area. The arm wound was quite healed.

On the evening of the eighteenth day the child collapsed, being blue and cold with gasping breathing. There was slight persistent twitching, but no definite convulsion or loss of consciousness. Stimulants revived her slightly, but at 12.45 a.m. on the nineteenth day she died after vomiting altered blood.

Post-mortem examination showed ample subcutaneous fat, healed scalds of abdomen and arm, and a small unhealed clean wound of the thigh. The cerebral vessels were much engorged, but there was no haemorrhage or excess of fluid. There was no evidence of pneumonia. The stomach was full of coffee-ground material. The vessels were engorged and the mucous membrane showed punctiform haemorrhages, but no ulcer was present here or in the duodenum, nor could any source of the blood be detected in the pharynx or oesophagus. No naked-eye evidence of septic absorption or degeneration could be seen.

At the inquest the father pertinently inquired why a child making such satisfactory progress should die so suddenly. A satisfactory answer to this question will be much appreciated.

Medical Superintendent, Booth Hall Infirmary.
Manchester.

ANAPHYLAXIS FOLLOWING INJECTION OF PITUITARY EXTRACT.

THE following case seems of sufficient interest to merit recording.

The patient was a married woman who suffered from a mild attack of lupus erythematosus, localized on the eyebrows and nose, and whose blood test by the Abderhalden method had shown an impairment in the function of the pituitary gland. I had prescribed and given to her injections of total pituitary extract. These injections were started on August 10th, 1929, at the rate of two a week, hypodermically. Five injections were given, with a definite improvement of her erythematoid patches. The patient had no ill effects after the injections, but complained of a little giddiness a few minutes later. I ascribed this to the presence of a certain amount of the posterior lobe in the solution.

The sixth injection was given on September 2nd. Twenty minutes afterwards the patient was taken suddenly ill at home with all the classical symptoms of anaphylaxis. Her eyes and face became puffy, her hands and feet were swollen, her respiration was characteristic, and a rash developed, covering the whole body. Itching was terrific. I gave her 2½ grains of calcium chloride, with the result that all the symptoms disappeared in twenty-four hours.

This was the first time that such an incident had occurred after dozens of injections of pituitary extract that I have given in the last four years, using always the same solution; but Fournier, Pomaret, Alexander, Besredka, and many other authors have described similar incidents when experimenting with infinitesimal doses of opotherapeutic extracts in the veins of animals, and it is therefore quite possible that a certain amount of the pituitary solution which I injected into my patient had been absorbed too quickly through a venule, thus producing an anaphylactic attack of urticaria. The patient, however, does not remember having been injected before with any sort of serum.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

SWANSEA DIVISION.

Estimation of the Basic or Diastolic Blood Pressure.

AT a meeting of the Swansea Division, at the Swansea Hospital, on December 12th, 1929, Dr. G. ARBOUR STEPHENS, consulting cardiologist to King Edward VII Welsh National Memorial Association, read a paper entitled "A new method of estimating the basic or diastolic blood pressure."

Dr. Arbour Stephens said that the importance of ascertaining the blood pressure demanded that the method of ascertaining it should be both simple and reliable, and he believed that his method complied with these requirements. The ordinary definition of the blood pressure was "that pressure which the blood exerts against the vessel wall in which it is contained." The speaker preferred, however, to define the blood pressure as "the pressure which the vessel walls exert on the blood inside them." He remarked that blood was composed of living cells which performed their work by exuding through the vessel walls; in order that the exudation might be satisfactory there must be a satisfactory blood pressure, or, in other words, the blood cells required an optimum pressure range. A knowledge of the systolic blood pressure was of little value without the diastolic, or what the speaker termed the "basic," blood pressure. The systolic pressure was fairly easy to determine by the present methods, but the determination of the basic or diastolic pressure presented difficulties to the majority of medical men. The optimum pressure range extended between the highest point of the systolic and basic pressures. The systolic pressure varied throughout the whole contraction of the heart muscle, whereas the basic pressure was relatively steady.

Determination of the basic pressure gave: a measure of the vasomotor tone; the lower limit of pressure commensurate with an adequate supply of blood to the vessel walls themselves; the constant pressure on the blood, to which the variable systolic pressure was additional; and an index of what the heart force had to overcome. The basic pressure was increased by: vaso-constriction; increased rapidity of the heart; increased intracerebral pressure, as, for example, in meningitis and tumour; and exercise. There was a consequent retention of products in the blood which tended to disturb the system. The basic pressure was lowered by: vaso-dilatation, as in fevers, neurasthenia, and hypothyroidism; heart-block; thickening of the arteries in the absence of increased capillary resistance; and aortic insufficiency.

The systolic pressure was estimated by means of the sphygmomanometer, and was just that pressure which was able to stop the pulse, or, in other words, that pressure

which stopped the driving onwards of the blood. The basic pressure was estimated by the tactile, oscillatory, vibratory, and auscultatory methods. The auscultatory method seemed to be the only one used at present, and depended on the recognition of the right sound at the right time during the deflation of the armlet. The chest-piece of the stethoscope had to be placed over the artery just below the armlet, in order to determine the correct sound. There were in this method several sounds to be considered—namely, murmurs, clicks, thuds, dull sounds, as well as the absence of any sound—but to say which sound was the true indicator was a matter of doubt and difficulty. There were admitted limitations of the auscultatory method, such as (1) in cases of irregular hearts there was a difference of intensity between successive sounds; (2) the arm might be covered with too much fat; (3) there might be no blood vessel large enough to auscultate; and (4) many doctors had no ear for differences of sounds, and were unable to detect the right sound at the right time, even if there was really a right sound. As to the sounds themselves, there was apparently no definite opinion regarding their nature or causation. It was said that the sounds were due to whorls in the blood vessel, but when it was recalled that a whorl had been defined as "a number of leaves round a stem," or "a turn in a spiral shell," it became evident that there was something wrong. The presence of a whorl of this sort would not be conducive to good health. There was obviously no whorl in the blood vessel of a living man. It was said that the sounds might be produced in the vessel wall, but how or why was unknown. If the muscular wall was responsible for these sounds, how was it that the weakened, ill-nourished wall of an anaemic patient can produce a very loud sound? Muscles, however, did not produce sounds when they contracted. In the speaker's opinion the sounds heard were those which were conducted from the heart; they were intensified when the stream was rapid or the pressure high, just as a toned or tautened violin string vibrated more readily than a slack one.

Dr. Stephens said that his method depended on a knowledge of the condition of the blood in the artery below the inflated armlet. When the armlet of the sphygmomanometer was inflated the artery below it was still full with blood under a certain pressure due to the vessel walls and the tissues generally. Many doctors thought that as soon as the pulse ceased to be felt, owing to the pressure of the armlet, the artery below the armlet became emptied, but they forgot that the armlet prevented the blood leaving the arm because it pressed on the veins as well. A statement of this sort might seem puerile, but teachers were not aware how badly their lessons were learned, even if they were given properly, and for this reason it was desirable to point out this common mistake. The artery below the armlet was full of blood from which the systolic pressure had been removed, leaving only the basic pressure, due to the tone of the vessel walls and tissues, to act on the blood. This point was of importance, and could be readily missed. A little pressure on this full artery by means of the finger caused the needle of the sphygmomanometric dial to move upwards. This occurred also when the chest-piece of the stethoscope was applied to the artery in the auscultatory method, and the pressure so introduced had much to do with the modification of the sound heard or conducted. This little additional pressure which made the dial needle move upwards could be measured by means of a second sphygmomanometer placed just below the first.

The procedure suggested was carried out as follows. The armlets of two sphygmomanometers were placed on an arm, one below the other. The upper armlet was inflated until the pulse ceased to be felt, and the reading on the upper dial gave the systolic blood pressure. The second armlet was then inflated until the needle on the upper dial was moved upwards one or two points, and the reading of the lower dial gave the basic blood pressure. The speaker added that his method was mechanical and objective, and required the minimum of skill and judgement, whereas the auscultatory method was not, in his opinion, based on scientific grounds, and depended on the capacity of the doctor to detect and discriminate between various sounds which were not readily heard.

Reports of Societies.

OVARIAN TUMOURS.

A MEETING of the Edinburgh Obstetrical Society was held on January 8th, with the president, Dr. H. S. DAVIDSON, in the chair. By invitation, Dr. J. W. BRIDE of Manchester read a paper on the investigation of a series of 100 cases of ovarian tumours.

Dr. Bride included in this series only tumours which could be considered as distinctly new growths, all cysts due to chronic ovarian inflammation and endometrioma having been excluded. The average age of the patients was 42 years, but 53 per cent. of these tumours appeared between the ages of 30 and 60, 72 per cent. occurring in women of over 30 years of age; the average age for carcinomata was 52, and for sarcomata 47. It was not found that ovarian cysts were more common in unmarried women than in married women; in the case of tumours in married women, 63.4 per cent. of these women were fertile. Abortions were met with in only 2.7 per cent., though miscarriages occurred in 20.5 per cent.—17.2 per cent. of these having also had full-term living children. In all, 59 of the tumours were cystic, 20 were solid, and 21 were malignant. Pseudo-mucinous cyst adenomata formed the largest number of tumours, there being forty cases. In no case of papillomata was ascites found, nor was hydro-peritoneum present in any of the three cases of solid fibromata, this being contrary to the usual teaching. Either ovary was equally affected, and in twelve cases both ovaries were implicated. With regard to symptoms there was very little disturbance of the menstrual function in simple cases, dysmenorrhoea being present only in 17 per cent., and menorrhagia in 15 per cent. It was also noted that in only three (14.2 per cent.) of the malignant cases was there irregular bleeding after the menopause, though such bleeding is often regarded as a feature of malignant growths. Pain was present only in 47 per cent. of cases of simple growths, but in the case of malignant growths, 66.6 per cent. of the patients complained of pain. Unilateral pain appeared to be a guide to the affected side. The most constant symptom was abdominal swelling, but there were a large number of patients who did not notice the swelling, or attributed it to fat or the menopause. Pain and frequency of micturition were present only in the case of simple tumours impacted in the pelvis, but such symptoms were present in 28.5 per cent. of malignant tumours where the bladder had obviously been involved secondarily. In the malignant cases ascites was observed in 52.3 per cent., but no cases of ascites were found with simple tumours. The greatest diagnostic difficulty was that between an ovarian cyst and a very large cystic kidney. Ovariotomy was performed in 43 per cent. of the cases, and subtotal hysterectomy with removal of both ovaries in 3½ per cent. Dr. Bride stressed the importance of performing a subtotal hysterectomy with removal of both appendages when both ovaries were definitely cystic or diseased, since the uterus, if left, might be the seat of malignant disease at a future date. Such a contingency had occurred in one case in the earlier part of his series, where Dr. Bride had performed a double ovariotomy, and had previously left the uterus *in situ*. The cyst was tapped eighteen times where an enormous incision seemed prejudicial, either on account of the condition of the patient or on account of a coexisting pregnancy. As regards complications, rupture occurred only in one case, but there was torsion of the pedicle in eleven, and in four of these during the puerperium.

With regard to malignant cases, the prognosis was found to be bad, though the operation seemed to hold out some hope of recovery; ascites appeared to be of very bad prognostic import. Dr. Bride advocated that, in large cysts in older women, the cyst should be separated from its adhesions to the parietal and visceral peritoneum by sweeping round the fingers before the cyst was tapped, if such a procedure had been decided upon. Secondly, before beginning to remove the cyst, the other ovary and the uterus should be inspected so as to save delay later on,

since a hysterectomy might be required instead of an ovariotomy. With regard to future treatment, careful attention should be paid to the tone of the bladder in the case of very large tumours. The mortality after operation in Dr. Bride's series was 5 per cent., in the simple cases 3.7 per cent., and in the malignant 9.5 per cent.; this compared favourably with Munro Kerr's series of 250 ovariotomies with a mortality of 4.4 per cent. Old age appeared to be no bar to operation. Five of Dr. Bride's patients were over 70 years old, and all did well.

DIAGNOSIS OF DISEASES OF THE ORBIT.

AT a meeting of the Aberdeen Medico-Chirurgical Society on January 16th, with the vice-president, Dr. HENRY PETERKIN, in the chair, Dr. W. CLARK SOUTER showed a series of lantern slides illustrating a number of recent cases of affections of the orbit. The material was classified as follows: a group of cases of acute and chronic ethmoidal infection with orbital implication; a series of cases of neoplasm of the antrum and outer wall of the orbit; a case of orbital tumour secondary to cancer of the breast; cases of head injury with fracture of the orbit; a case of osteoma of the medial orbital wall; and a group showing orbital cellulitis. Dr. Souter pointed out the diagnostic value attached to the secondary displacement of the eye in cases of proptosis where the cause was not simply in the orbital connective tissues. In his photographs he demonstrated downward displacement due to tuberculous periostitis of the upper wall of the orbit, outward displacement with osteoma of the medial wall, inward displacement with sarcoma of the outer wall, upward displacement where an epithelioma of the antrum had invaded the floor of the eye socket, and several cases of acute ethmoidal suppuration where the displacement was both downwards and outwards. The lecturer said that radiographical and rhinological examination were of the greatest help in all cases of acute orbital inflammation as well as in many other lesions in the immediate neighbourhood of the orbit. Anatomical preparations lent by Professor Low and Dr. R. D. Lockhart were shown to illustrate the anatomy of the orbit and the structures surrounding it.

ILLUMINATION AND PRINT.

A MEETING of the Section of State Medicine of the Royal Academy of Medicine in Ireland was held on January 17th, when the president, Professor W. D. O'KELLY, read a paper on illumination and print.

Professor O'Kelly dealt first with illumination, and discussed the necessity for fixing standards of adequate and correct illumination and not merely minima. The question of obliquity of illumination was illustrated by slides showing the diminution in the amount of light falling on a book when tilted so that light no longer fell on it at right angles to the source; it was shown that in many cases an object was only receiving indirect and often totally inadequate illumination. The questions of glare and its avoidance and of surface brightness were then considered. In connexion with the lighting of schools the speaker suggested that a foot candle meter should be used on a dull day, actual readings being taken in the rooms. The provision of artificial lighting in schools was essential in most cases on dull days; no pupil should be condemned to sit the whole year in a badly lighted place, and pupils should change their positions during the day unless the conditions were ideal. Installation of artificial illumination could not be considered as being an alternative to adequate daylight, but merely a stopgap arrangement in existing buildings. In the section dealing with print Professor O'Kelly discussed first the question of faces and sizes of type, and showed the difficulty, for the non-technical person, of determining what size of type was used in a given case. The standards laid down in other countries specified the minimum height of the small letters, and the speaker agreed that children under the age of 12 (but not beginners) should not be allowed to use school books with small letters less than 1.75 mm. high, or less than 1.55 mm. high at any time during school life. If it were necessary to economize he would prefer a page and type twice the size printed on a cheaper paper. One of the objections to the use of small type was that the ascending and descending parts of the letters were reduced more than the remainder. The eye picked out in reading the upper part rather than the whole letter, and, since all the capitals were ascending letters, and ascending lower-case letters occurred more frequently than descending ones, it was rendered doubly difficult for the child to read small type. When the eye was fatigued and the illumination insufficient a great strain was thrown on the eye, and damage frequently resulted. The Irish type was pleasing to the eye. Irish texts set up in Roman type did not look so well, especially when "h" was substituted for the aspirate mark. Professor O'Kelly did not think the Irish type would be replaced by the Roman for this reason, any more than would the Venetian black letter have replaced the English black letter, although the former was a simpler type; it had, however, a very ugly face. The Gothic varieties, although more difficult, were more ornate and pleasing. The communication was illustrated with lantern slides and specimens of print of various sizes and faces.

Dr. W. C. MACFETRIDGE agreed that the question of the illumination of school buildings was very important, but the illumination of blackboards was sometimes entirely neglected. The importance of the illumination of buildings in general was not fully realized; it should be remembered that the proportion of the population working in buildings was very large and was becoming larger. Dr. M. O'LEARY said that even in schools which conformed to the rules laid down by the Local Government Department the percentage of cases of bad vision was nearly as high as in those which did not. It had recently been stated that 50 per cent. of the eye troubles in children were hereditary and were not in any way due to faulty illumination in the schools. Dr. R. J. ROWLETTE said that the Local Government Department in its regulations had now demanded a report as to the lighting of schools to be included in the work of school inspectors; he thought that in doing this the department was going beyond the powers which had been given them by the Act, which did not relate to the inspection of schools, but to the inspection of school children. He hoped that school medical officers would in the future be given much more power. The surface of the paper supplied in many journals and books at present—glazed paper—was extremely irritating. The reason for this was, perhaps, to save the printer using two different types of paper, one for the text and one for the illustrations. This tendency should be criticized in the hope that publishers would consider the eyesight of their readers.

The PRESIDENT, replying, said that the illumination of blackboards in schools was a great source of trouble. More care was now being taken to see that all modern buildings were efficiently lighted. He thought that medical officers of health could object to some of the school buildings on the ground that the light was insufficient to enable them to inspect the school children.

CAPILLARY HISTOLOGY OF THE SPLEEN.

AT a meeting of the Liverpool Medical Institution, on January 16th, Dr. R. H. MOLE read a paper on the histology of the vascular system of the dog's spleen, based on work in the pathological laboratory of the Medical College, Mukden, Manchuria. Drs. P. L. Li and H. S. D. Garven had collaborated in the work and in the writing of the paper.

Dr. Mole said that the spleens of ten dogs were distended by partially clamping the veins, and were washed out with saline or Ringer's solution in the distended condition. The red blood corpuscles of chickens, or Indian ink, were injected either into the artery or into a vein. The spleens of a stillborn baby and of a pig were similarly treated. The organs were fixed *in situ*, and preserved in formol. Serial sections were made, and various staining

methods, including silver impregnation, were employed. It was found that the artery when it left a trabeculum to enter the pulp was a four-coated artery, the outer coat being composed of trabecular tissue. This became a three-coated vessel by intermingling of the adventitia with trabecular coat. Four-coated and three-coated arteries might acquire Malpighian corpuscles, as well as two-coated arteries after the disappearance of the adventitia. The Malpighian corpuscles seemed to be situated where branches left the artery, and might provide a mechanical support for the artery at these points. The *penicillia* or subterminal capillaries had an endothelium and a thin connective tissue sheath external to this. Each penicillar branch acquired one or more ellipsoids. The ellipsoids were sheaths surrounding the capillary, composed of reticulo-endothelial cells with a small amount of reticulum. The innermost layer of cells was attached to the capillary wall by cell processes. The ellipsoid cells contained greater aggregations of iron pigment than did the cells of the pulp. The ellipsoid capillary, after emerging from the ellipsoid, bifurcated, and ended in the so-called "blind chamber," which was lined in its terminal part, not by endothelium, but by reticulo-endothelial cells. The ellipsoids were in close relation to the venous sinuses. The ellipsoid capillary was the narrowest part of the arterial system. No openings were observed in the wall of the ellipsoid capillary of the dog or of the baby, but these were evident in the capillary wall of the pig's ellipsoid.

No evidence was found of direct arterio-venous communication, though plasma passing through the gaps in the wall of the pig's ellipsoid capillary might flow directly into a venous sinus. Small particles escaped through the wall of the ellipsoid capillary, and were taken up by the cells of the ellipsoid sheath. In the spleens injected with Indian ink the peri-Malpighian zone and the ellipsoids appeared black with carbon particles. Ellipsoids were particularly found at the periphery of the Malpighian corpuscle. A distinct peri-Malpighian blood zone existed, since chickens' corpuscles and Indian ink injected through the artery were found chiefly in this situation. Into this zone three sets of capillaries opened: (1) derived from its own Malpighian artery, acquiring ellipsoids, bifurcating and turning back in a recurrent manner; (2) derived from its own Malpighian artery, which opened into it without acquiring ellipsoids; and (3) derived from the arteries of other Malpighian corpuscles. Venous sinuses were absent in this peri-Malpighian blood zone. The wall of the venous sinus had an outer layer of coarse, transversely arranged reticulum, and an inner layer composed of reticulo-endothelial cells lying at right angles to the transverse reticulum. These cells, together with their processes, formed, with the reticulum, the fenestrations of the sinus wall. The cells might control the size of the fenestrations. Splenic contraction caused blood to pass by pressure from the pulp to the venous sinuses. Suction had also a part to play, since splenic contraction must dilate the veins owing to the connexion of their walls with the capsule.

At a meeting of the Optical Society on January 16th Mr. J. N. MORRIS, of Messrs. Raphael's, Ltd., demonstrated a visual test involving a new system of equi-photic illumination. The apparatus shown was the drum type, illuminated by strip lights contained within a lamp tube of a length approximately equal to that of the Snellen chart on each face of the drum, the tube being placed about twelve inches in front and a short distance at the side of the chart. This arrangement gave perfect illumination in the vertical meridian; uniformity in the horizontal meridian was secured by making the horizontal section of the drum slightly concave. Mr. J. COLE, of the same firm, exhibited scientype occluding glasses for use in the treatment of squint. One side of the spectacle glasses had one surface regularly patterned with depressions, which were so arranged that the vision of the corresponding eye was reduced without alteration of its external appearance. In order to compel the deviating eye to make the effort to see, it was necessary to reduce the vision of the fixing eye below that of the deviating one.

Reviews.

BACTERIOLOGY AND IMMUNITY.

THE recognition of the importance of bacteriology, not only in its application to human and veterinary medicine, but also to agriculture and many industrial processes, entails the training of an ever-increasing number of individuals in this science. The elementary instruction in bacteriology given to the medical student, and even that of the D.P.H. syllabus, is inadequate for this purpose, and in order to cater for this demand the diploma course in bacteriology has been evolved. Students of this category require an adequate textbook with which to guide and augment their studies, and up till now a book of this nature has not been available in the English language. It is fortunate, therefore, that Professor W. W. C. TOPLEY, through whose initiative the diploma course has come into being in this country, should have decided to supply this need, and we heartily welcome the appearance of *The Principles of Bacteriology and Immunity*,[1] written by him in collaboration with his colleague, Dr. G. SELBY WILSON. This book is divided into two volumes, the first of which deals with the purely scientific side of bacteriology, the second with its applications to animal pathology. At first sight this division may strike the medical reader as somewhat unusual and awkward, for in volume i he will find, say, the typhoid-paratyphoid group discussed as a purely botanical problem, whereas the disease states produced by them in man and other animals are dealt with in volume ii; the usual procedure would have placed the two sections together. This latter method of dealing with the problem has its origin in the fact that bacteriology has developed very largely as an applied science; it is only comparatively recently that an effort has been made to remedy this one-sidedness. The authors are primarily concerned with presenting bacteriology as a science, and it is this attitude which is responsible for the unusual division of the subject found in the two volumes; there is much to commend it.

Volume i is divided into two parts—general bacteriology and systematic bacteriology. The former opens with an excellent, though brief, historical outline and then proceeds to deal with the morphology of bacteria, their physiology, growth and death, resistance and disinfection, the serum reactions, bacterial variation, the classification of bacteria, methods of isolation and identification, and the Twort-d'Herelle phenomenon. The chapter on the physiology of bacteria is very good. This is a branch of the subject which, though of fundamental importance, has been persistently neglected, and we are glad to find it so clearly dealt with here. It would have been better, perhaps, in the chapter on disinfectants if the work of Geppert had been given more than a mere reference. He drew attention to a fundamental error in the testing of the action of antiseptics which has been largely ignored by subsequent workers, as Bulloch has had reason to point out in his researches on catgut. It is a pleasure to read an account of the serum reactions which is at once so clear and well balanced. The hypothesis of Ehrlich, which for so long has dominated this subject, is adequately discussed, but not to the detriment of alternative views. The sections on the antigenic structure of bacteria and bacterial variation are admirable. When dealing with the classification of bacteria the American nomenclature has been adopted with but few alterations. Everyone will agree with the authors when they deplore the chaotic state into which bacterial nomenclature has fallen, and there is much to be said for the American system, but doubtless many will think the authors' adoption of it premature. The second part of this volume is concerned with descriptions of the different bacterial species. It is clearly put out and well illustrated, and terminates with a short but well-balanced account of the filterable viruses.

[1] *The Principles of Bacteriology and Immunity.* By W. W. C. Topley, M.D., M.Sc., F.R.C.P., and G. S. Wilson, M.D., M.R.C.P., D.P.H. In two volumes. London: E. Arnold and Co. 1929. (6½ × 9½, vol. i, pp. xvi + 537 + xvi; 163 figures; vol. ii, pp. viii + 713 + xx; 74 figures. 50s. net the two volumes.)

Volume ii treats of applied bacteriology. Like the first volume it is divided into two parts, the first on infection and resistance, the second on the applications of bacteriology to medicine and hygiene. It is difficult to find material for criticism. The same clear exposition which characterized the first volume is not lacking here. One turns instinctively to such a question as the diagnosis of enteric infections, because to the bacteriologist concerned with routine diagnosis, who has become lost in the maze of the antigenic complexity of the typhoid-paratyphoid group, this is rather a thorny problem. Even here, however, there is no ambiguity. Clear indications are given as to how this problem should be tackled, and, though nine different suspensions are required, the logical necessity for so many is clearly indicated. In dealing with infection with the virus of herpes it is perhaps unfortunate that experimental work with the rabbit should have been given undue prominence. Herpes is a disease of man characterized by a localized vesicular eruption, and this condition can be reproduced in rabbits and guinea-pigs by applying the vesicle fluid to the scarified skin. The lesions produced are no more insignificant than in man, and the encephalitis which follows corneal implantation in the rabbit, though interesting, is a peculiar accident of the experimental disease. This, however, is a minor point, and, generally speaking, the virus diseases are well and critically treated.

The authors' task has been an extremely difficult and arduous one, for in the present state of bacteriological knowledge it is no mean undertaking to keep in touch with all the different lines of progress. They have read widely and critically, and a short though useful bibliography is appended to each chapter. The book is admirable in its conception and excellent in its execution, and should prove of the greatest service, not only to the post-graduate student of this subject, but also to bacteriologists in general.

NEUROLOGICAL STUDIES.

WHEN Dr. GUILLAIN publishes a series of papers on neurology we expect good quality, and in this third series of *Etudes Neurologiques*[2] we are not disappointed. The work is divided into eight parts, devoted to cerebral tumours, to the pathology of the brain, spinal cord, and cranial nerves, to the muscular trophies, and to several miscellaneous subjects. The studies have all been carried out at the Salpêtrière, and all the cases have been presented in the author's clinics. Most of the papers had previously appeared in the *Revue Neurologique*.

In the section devoted to cerebral tumours the first three chapters are concerned with cerebral cysticercosis, and Guillain emphasizes the great value of the examination of the cerebro-spinal fluid. He then describes a glioma of the corpus callosum, a median cyst of the third ventricle, in which the tumour was entirely limited to the cavity of the third ventricle itself, a fibro-glioma of the anterior pillars of the trigone, multiple metastatic melanotic sarcomata, and an angio-glioma of the cerebello-pontine angle. The next two chapters describe the pure motor and sensory aspects of the nervous system; in the first, Guillain cites extra-cortical Jacksonian epilepsy, and in the second, a softening of the parietal lobe giving rise to well-marked sensory symptoms.

The next portion of the book is given over to a variety of lesions in the region of the cerebral pedunoles, pons, and cerebellum. The chapter on olivo-ponto-cerebellar atrophy is particularly good, and represents the French school of neurology at its best. This chapter is followed by a study of syphilitic progressive cerebellar atrophy; a section on a variety of lesions of the spinal cord—syphilitic, traumatic, neoplastic, and otherwise; and a section on the cranial nerves, illustrated by some excellent radiograms of the skull, which serve to show very forcibly the importance of making complete examinations in all cranial nerve lesions.

The book is extremely well illustrated, and it may be regarded as a presentation well worthy of the Salpêtrière.

DIVERTICULA OF THE BLADDER.

THE second edition, now issued, of Professor BLUM'S excellent and authoritative monograph on the Surgical Pathology and Treatment of Diverticula of the Bladder[3] incorporates the results of the eight years' experience gained since the first appearance of the book. The subject has been closely studied by surgeons during that period, and more than three hundred works have been published in connexion with it. From the author's account there appears now to be a general consensus of opinion as to the nature of diverticula and their surgical treatment.

Leaving out of account the small, multiple pressure-sacculi which are met with in hypertrophied and fasciculated bladders in cases of chronic obstruction, it is now considered that diverticula have a congenital basis in the form of weak areas in the bladder wall, more especially in the neighbourhood of the ureteric openings and at the apex of the bladder. The diverticulum is formed by the gradual yielding of the weak area; it may apparently remain latent for many years, but finally gives rise to characteristic symptoms, and if untreated induces fatal complications. Such appears to be the regular course of the affection. The fact that the onset of symptoms may be delayed until a comparatively advanced period of life led to the belief that early operation was unnecessary and unjustifiable, and that the patient might be permanently tided over complications by suitable palliative treatment. According to the experience of Blum and other surgeons this view is untenable; a fatal termination is to be anticipated sooner or later, and accordingly the rule is laid down that as soon as the diagnosis of a diverticulum has been securely made a radical operation should be carried out if possible. The ideal operation is the suprapubic, extra-peritoneal isolation and extirpation of the diverticulum without opening the bladder. This is applicable to diverticula of the apex and the anterior, lateral, and posterior walls; it is not suitable for those connected with the base of the bladder occupying the hollow of the sacrum. According to the author the latter are best treated by Pagenstecker's sacral operation, Kreuter's perineal section, or the parasacral method of Völker. Other possibilities are the transperitoneal and transvesical routes.

Blum's book is probably well known to those more especially interested in genito-urinary affections; it gives a complete account of the diverticula in their etiological, pathological, clinical, and surgical aspects.

HYDATID DISEASE IN AUSTRALIA.

THE *Collected Papers*[4] of the Walter and Eliza Hall Institute of Research in Pathology and Medicine in Melbourne for the period 1927-29 naturally include much new and important work on hydatid disease. General surveys of the great prevalence of this disease are given by Dr. N. Hamilton Fairley and Mr. J. S. Penrose, and a very pessimistic note is struck in the matter of prophylaxis on account of the laxity of the regulations in the smaller abattoirs and the difficulties of effective educational propaganda. Indeed, it is said that until the regulations are materially strengthened in the matter of the disposal of slaughterhouse offal "no substantial decrease in the incidence of hydatid disease in herbivora and man can reasonably be anticipated." The ease with which complete taeniae can be obtained from dogs taken at random from the streets, and the comparative failure of the order making hydatid disease notifiable, are commented upon in strong terms, and a plea is made for nation-wide grappling with the problem. The same authors, in assocation with Dr. R. J. Wright-Smith, give a pathological survey of hydatid infestation in sheep, oxen, and pigs, with special reference to pathological anatomy and the evolution of exogenous cysts. Diagnostic tests in hydatid disease are discussed by Dr. C. H. Kellaway, the director of the institute, who contributes also shorter papers on the source

[3] *Chirurgische Pathologie und Therapie der Harnblasendivertikel.* Von Professor Dr. Victor Blum. Zweite, vermehrte und verbesserte Auflage. Leipzig: G. Thieme. 1929. (6½ × 10, pp. 157; 77 figures, 5 plates. M. 13.50.)

[4] *Collected Papers.* The Walter and Eliza Hall Institute of Research in Pathology and Medicine, Melbourne, 1927-29. Vol. iv. (Med. 4to.)

and nature of the hydatid antigen. The Casoni diagnostic test resembles somewhat the original tuberculin test, and has a high range of utility and efficiency. In the institute the test used as a routine was devised by Dr. Fairley, and is akin to the Wassermann reaction. A good many other tests based on dermal sensitiveness are under investigation.

There is a very instructive and interesting article by Mr. H. R. Dew on hydatid anaphylaxis. The symptoms of this are extremely variable, and are due to the presence of some degree of sensitization which a patient experiences when he harbours a cyst and absorbs therefrom varying amounts of specific hydatid antigen. Anaphylactic phenomena may be provoked by trauma, puncture, or surgical intervention, by suppuration, or by anything that permits the leakage of fluid. There are often small unnoticed leaks from deeply placed visceral cysts, and the effect of these leaks will depend on the extent of the patient's previous sensitization. Five types of anaphylactic manifestation can be recognized. Pruritus, urticaria, and erythema are, of course, well known. Gastro-intestinal disturbances may be very severe. The severity of the dyspnœa and pulmonary œdema may exceed that seen in any other anaphylactoid condition. Cardio-vascular collapse may be alarmingly sudden; and, finally, nervous conditions include convulsions, delirium, and coma. From his studies Mr. Dew draws a number of practical conclusions. In the first place he emphasizes that exploratory puncture of even a simple cyst may be fatal through anaphylaxis. The matter is extremely difficult because the degree of sensitization varies very much in different patients, and means of determining this sensitization are, as yet, not fully elaborated. The sensitization is certainly highest during the two or three weeks immediately following some structural change or traumatic interference with the cyst. Secondly, general anæsthesia, so far as the prevention of anaphylaxis is concerned, is preferable to local anæsthesia, but delayed anaphylactic reactions are possible after general anæsthesia if insufficient care is employed in the isolation of the cyst fluid. These practical studies are supplemented by Dr. Kellaway on the lines of experimental medicine, with special reference to the hydatid antigen and the theoretical aspects of hypersensitiveness.

SLEEP AND HYPNOTICS.

WE have received a volume[1] of 167 pages, containing short monographs on sleep by various teachers of the Viennese school. The editor, Dr. SARASON of Berlin, contributes a preface in which he indicates the great importance of hypnotics, and also puts forward a reasoned defence of symptomatic treatment. His argument is that in every disease some vicious circle becomes established, the exact form of which varies in every patient. The initial aim of treatment should be to find and to treat the weakest point in the circle, and thus relieve the patient preparatory to attempting to treat the fundamental cause of the disease. Following this line of reasoning, Dr. Sarason considers the production of sleep and the allaying of pain as two of the most important benefits that the doctor can confer on his patients.

Professors Pötzl and von Economo contribute a series of articles on the psychology and physiology of sleep, and give a short account of the views of the Viennese school. These views are to a large extent based on the careful study of encephalitis lethargica that has been carried out in Vienna. Professor Pick and Dr. Molitor deal with the pharmacology of hypnotics, a subject upon which they have done a large amount of original work. Their opinions are based on the belief that there is a sleep-regulating centre in the mid-brain, a centre that is controlled by the cortex. They divide hypnotics into two classes, those that act chiefly on the cortex and those that act directly on the mid-brain centre. Chloral hydrate and paraldehyde are examples of the former class, while most of the derivatives of barbituric acid and also chloretone belong to the latter class. They believe that it is advantageous to combine hypnotics belonging to two classes—for example, paraldehyde and chloretone—because narcosis can thus be induced with a smaller total dose of hypnotics. They agree that the ideal hypnotic has still to be discovered, but they point out that the number of fairly satisfactory hypnotics is remarkably large, and the doctor has a very wide choice in this field of therapeutics.

THE STHENICS.

SIR JAMES KINGSTON FOWLER writes so pleasantly and can turn an epigram so adroitly that his recent utterance, *The Sthenics: the Chord Incisible*,[2] will attract readers to find out the meaning of this cryptic title. The sthenics he defines as hypersensitives, or those whose nervous systems are more highly sensitized than the average, and yet they are not neurotics or neurasthenics: they are endowed with great vitality and power of work, fertile imagination, clear vision, and wide interests; but they are not good judges of character, do not inspire complete confidence or affection in their subordinates, as they are not considerate and are prone to reject able men who might detract from their own glorification. Physically the hypersensitive skin and mucous membranes may cause pain, muscular spasms, asthma, and nervous attacks, liable, as in the case of Napoleon, to be erroneously regarded as epilepsy; these attacks are, it is suggested, due to excessive discharge of adrenin into the circulation. An interesting analysis of the characteristics of Napoleon, Lord Curzon, and Sir E. Marshall Hall leads to the conclusion that they were sthenics, and that Lord Haldane and Lord Moulton were not.

NOTES ON BOOKS.

DR. C. F. BOLDEAN'S work on *Public Health and Hygiene*,[3] which is appropriately dedicated to the late Dr. Hermann Biggs, a former general medical officer of the New York City Department of Health, forms an excellent introduction to the study of the subject. The book is divided into five parts. The first consists of five chapters, dealing respectively with the historical aspects, micro-organisms and disease, the transmission of communicable diseases, the life-history of certain important insects, and disinfection. The second part contains fourteen chapters on the principal communicable diseases. In the third part other important preventable diseases and conditions are discussed, such as nutritional disorders, diseases of middle and later life, endocrine disturbances, mental disorders, and accidents. In the fourth chapter the various branches of community hygiene are considered, such as the water and milk supplies, sewage disposal, ventilation, industrial hygiene, infant welfare, school medical inspection, and quarantine. The fifth part is devoted to epidemiology.

The third edition of Tropical Diseases and Hygiene,[4] by RUGE, MÜHLENS, and ZUR VERTH, preserves the high standard of its predecessors. The volume is intended primarily for the practitioner, and so the section on formal hygiene is limited in extent and treatment to 53 pages out of a total of nearly 500; it deals briefly with climate, housing, water, and such subjects. The remainder of the book deals with tropical diseases. Commencing with a consideration of the blood, it continues with malaria, trypanosomiasis, and leishmaniasis. This is followed by amœbiasis and diseases due to other protozoa and to spirochætes. The succeeding sections deal with metazoan parasites; skin conditions; poisonous animals and plants; tropical surgery; and with cosmopolitan diseases, which are as important in the tropics as in temperate lands, and often much more so. The book contains nearly five hundred illustrations, not only of the causal organisms of the various diseases, but also of clinical conditions. There are included among these illustrations many graphs and charts of considerable value; while at the end of the volume are several coloured and half-tone plates of the blood, blood organisms, and helminth eggs. Many of the illustrations are drawn from the collection of the Hamburg Tropical School. The volume is printed on a heavy glazed paper; it is very well produced, and is unusually free from errors. It should continue to be of great service to German-reading practitioners in the tropics.

[3] *Public Health and Hygiene.* By Charles Frederick Boldean, M.D. Philadelphia and London: W. B. Saunders Company. 1929. (8½ × 5½, pp. 732; 122 figures. 12s. 6d. net.)

[4] *Krankheiten und Hygiene der Warmen Länder.* Von Professor Dr. Reinhold Ruge, Professor Dr. Peter Mühlens, Professor Dr. Max zur Verth. 3. vollständig umgearbeitete Auflage. Leipzig: G. Thieme. 1929. (Sup. roy. 8vo, pp. x + 494; 488 figures, 8 plates. M.33.60.)

Applied Anatomy,[9] by G. G. DAVIS, and revised by G. P. MULLER, has reached its eighth edition, and the new edition retains the high standard of its predecessors. This treatise on the clinical application of anatomy is well known. It may be earnestly recommended for the use of students and clinicians as a book of great practical value. Moreover, it is a convincing exposition of the fundamental importance of anatomy in relation to the pathology and treatment of diseases and injuries. We may not agree with the claim in the preface that "this book has occupied a unique place in surgical literature," but we readily believe that it has not been surpassed in its own line. We would suggest that in future editions the sections on the brain and spinal cord be brought up to the same level of excellence as the rest of the book.

The *Laboratory Guide to Vertebrate Dissection*,[10] by A. B. APPLETON, is designed for students who are taking the curriculum in anatomy for the Natural Science Tripos in the University of Cambridge. This is essentially a practical dissection manual, and the author has confined himself to giving the necessary instructions for such gross dissections of vertebrate types as the average student may reasonably be expected to carry out. The vertebrate types have been reduced to a minimum, examples of specialized groups, such as birds, being purposely omitted. An equivalent book for use in New York University, by M. E. LITTLE and R. T. KEMPTON, is called *A Laboratory Manual for Comparative Anatomy*,[11] and thus, as its title indicates, has a wider scope. This manual deals not only with the gross dissection of vertebrate types (including the alligator, which is too expensive and difficult to obtain for use in this country), but with osteology and the histological study of tissues. The method employed in this book, of dissecting one type as a whole by way of introduction, and subsequently studying other vertebrates systemically instead of systematically, is to be commended. The practical objections to such a scheme of work are adequately met in a useful appendix.

Properties of Food,[12] by W. M. CLIFFORD and V. H. MOTTRAM, is a small handbook of qualitative food analysis. It is written in a delightfully simple and entertaining style, and we feel sure that, by following the directions which it contains, the reader could obtain a very definite insight into the composition of the common foodstuffs. The authors have been at great pains to describe how best the necessary outfit of chemicals and reagents can be obtained (they put the total cost at about £2). We cannot help feeling that, to students of domestic science, the knowledge gained by working through this simple course of experiments would be worth many hours' attendance at lectures to which no practical work was attached.

CORRECTION.

We regret to find that the publishers of Jellett and Madill's *Manual of Midwifery* were incorrectly stated in a footnote to our review in the *Journal* of January 25th (p. 154). This book is published by Messrs. Ballière, Tindall and Cox.

[9] *Applied Anatomy*. By Gwilym G. Davis, M.D. Revised by George P. Muller, M.D. Eighth edition. London: J. B. Lippincott Company. 1929. (Sup. roy. 8vo, pp. xii + 637; 631 figures. 42s. net.)

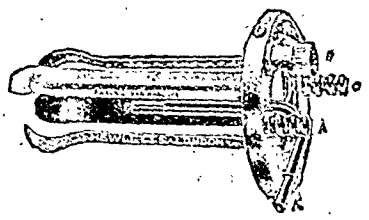
[11] *A Laboratory Manual for Comparative Anatomy*. By Malcolm E. Little and Rudolf T. Kempton. New York: The Macmillan Company; London: Macmillan and Co., Ltd. (Demy 8vo, pp. xix + 286; 19 plates. 10s.)

[12] *Properties of Food*. By W. M. Clifford, M.Sc.Lond., and V. H. Mottram, M.A.Cantab. London: University of London Press, Ltd. 1929. (Cr. 8vo, pp. 128; illustrated. 2s. 6d.)

PREPARATIONS AND APPLIANCES.

A MODIFIED FARABEUF'S RASPATORY.



LIEUT.-COLONEL J. N. DUGGAN, I.M.S., writes: The accompanying illustration shows a modified form of Farabeuf's raspatory made for me by Messrs. Down Brothers, Ltd., St. Thomas's Street, London. The standard form of rugine designed by Farabeuf of Paris for use on the long bones was

found to bring the hand somewhat inconveniently near the work, while the longer rugines designed by Pierpoint and Mitchell are rather heavy for fine work round the orbit, and it is thought that the rugine illustrated above will be found convenient for the delicate and precise work which falls to the lot of an ophthalmic surgeon.

THE VAGINASCOPE.

Dr. EDWARD BARON (London, N.) writes: I have devised an instrument, named the vaginascope, which is illustrated here in the open position; it eliminates many of the disadvantages of the specula in use. In the closed position it is of small cross-section, and can be introduced painlessly, the patient being either in the dorsal or the lateral position. Illumination is provided by a bulb attached to a battery and flex by means of a long tube running in a groove along one of the blades. A slight up-and-down movement at K makes or breaks electrical contact. Excellent visibility is obtained of the whole tract, including the vagina, cervix, cervical canal, and fornices, by loosening screw knob B, then placing the thumb on peg A and the forefinger on B; a single grip effects a simultaneous outward and parallel movement of the four blades, resulting in a rapid dilatation of the vagina. Full dilatation having been obtained, screw knob B is tightened, thus locking the instrument. Additional expansion and increased field of vision at the inner end of the vagina are obtained by the bulbous extremity of the instrument, which also makes the vaginascope self-retaining. Owing to this, and to the electrical illumination incorporated in the instrument, no assistant is required to hold the vaginascope in place, and the hands of the examiner are free to use additional instruments. On completion of the examination for diagnostic or therapeutic purposes, the screw knob B is loosened; then, gripping B and C, a single movement tends to close the instrument, which is easily removed in its partially closed form.

This vaginascope provides a compact, self-retaining, and self-illuminating speculum. It is made, complete in case with battery and flex, by Messrs. C. J. Hewlett and Son, Ltd., 35–42, Charlotte Street, W.C.2.

TABLETS OF STANDARDIZED DIGITALIS LEAF.

Messrs. Allen and Hanburys' tablets of digitalis leaf A and H are a preparation of powdered digitalis leaf, which is standardized physiologically. Each tablet contains 0.033 gram (1/2 grain) of international standard digitalis leaf, equivalent to 1/3 of an international unit. The recognized daily dose is 1/3 to 1 international unit—that is, one to three tablets. Although the *British Pharmacopoeia* of 1914, which is still current, does not recognize biological standardization, yet the necessity for such standardization has been generally acknowledged in the case of digitalis preparations. Powdered digitalis leaf is very widely employed on the Continent and in America, but in this country the tincture is generally preferred. On this account there are comparatively few reliable and convenient preparations of the powdered leaf available, and the preparation under notice is therefore a welcome addition.

ANIMAL PRODUCTS.

The price list of Messrs. Armour's glanoid compounds for January, 1930, contains descriptions of a large variety of animal products, such as endocrines, peptones, ligatures, digestive ferments, etc. The endocrine preparations are the most important feature, and about thirty of these are listed. The list reflects in a striking manner the present position of endocrinology. Apparently Messrs. Armour have adopted the principle of giving the medical profession what it asks for, and as a result preparations of the most varying status are listed. There are a number of preparations of well-established therapeutic value, such as liver substance, pituitary extract, thyroid, suprarenalin, etc. At the other end of the scale are preparations such as bronchial (lung) substance, cardin (heart) substance, cerebrinin (brain) substance. It seems a pity to include preparations of such wholly different status in a common list, for this association seems unfair to substances whose value has been proved by exact scientific and clinical tests. Included with the price list is a brochure giving an account of recent work by Professor von Zumbusch of Munich. Results obtained in his school indicate that hypodermic injection of large doses of spleen extract produces a beneficial effect in chronic eczema, in pruritus, and in urticaria.

PEROXIDE STICKS.

Peroxtik (Arthur H. Cox and Co., Ltd., Brighton) is peroxide of hydrogen dissolved in a substance of semi-solid consistency. It contains a 10-volume strength of hydrogen peroxide in stable form. The preparation as sold is made up in stick form, and is intended for application to the skin as an antiseptic or haemostatic, and also can be used for bleaching superfluous hair.

British Medical Journal.

SATURDAY, FEBRUARY 8TH, 1930.

THE EARLY DIAGNOSIS OF JUVENILE RHEUMATISM.

OUR vital statistics are bringing into increasing prominence the part played by heart disease in limiting the duration and full enjoyment of human life. In this country at all events, and in others sharing similar climatic conditions, many cases of this disease follow the rheumatic infection of childhood, or, to use Dr. Reginald Miller's brief and expressive term, "juvenile rheumatism." The widespread interest in the prevention and arrest of this infection reflects a growing recognition of the fact that it is a serious menace to the national health. Undoubtedly it is to prevention that we should devote the greater part of our energies if the problem were merely economic. It has, however, a humanitarian aspect, which presses heavily on the attention of the medical profession. This aspect is brought home daily to everyone working in the medical wards of our great hospitals. In one bed is a child in an early phase of rheumatic heart disease, in the next a young woman dying of mitral stenosis. How is the child to be saved from a similar fate? The more this kind of question is considered the more urgent seems the need to carry the possibility of diagnosis further and further back in the course of the disease. It is to this problem that the two addresses on juvenile rheumatism reported elsewhere in this issue are devoted. The two speakers—Dr. Carey Coombs and Dr. Reginald Miller—have approached it from slightly different aspects. The first has in his mind the damaged heart, the second the sick child. Yet both arrive at similar conclusions and emphasize the same lessons.

Recent studies, such as that by Dr. A. F. Bernard Shaw, lately published in the *Archives of Disease in Childhood*,[1] have brought new evidence in support of the view upheld by the last generation of British physicians—Cheadle, Lees, and their contemporaries—that the rheumatism of childhood is a generalized disease which must not be considered as a form of polyarthritis with cardiac complications, but rather as an infection which is dangerous to all the organs as soon as it enters the body. Dr. Miller thinks that there is a prodromal period during which this invasion may be detected before serious harm is done, and he directs attention to the various symptoms that may arise in that period. These he divides into four groups—the constitutional symptoms, the "throats and pains" group, the nervous disturbances, and, lastly, the symptoms of cardiac disease. He lays stress on the indefiniteness of many of the symptoms that may be presented by the rheumatic child, but claims that together they constitute a picture that can be recognized by the experienced observer. He does not, however, believe much in the diagnosis of a pre-rheumatic type—of a child foredoomed to rheumatic infection—as a practical measure. Dr. Carey Coombs's four categories of children in whom an early diagnosis of cardiac rheumatism may be made are a little different. There are children with frank rheumatism, whether of joints or of brain; those with tonsillitis; those with vague ill health; and a small group with cardiac symptoms.

In spite of these divergences in detail, it is clear that both Dr. Miller and Dr. Coombs view the task of reducing the ravages of cardiac rheumatism in the same way. The condition, they insist, must be regarded as a general infection with serious local manifestations. In all attempts to save vital organs from serious damage by infective agents there are certain principles to be observed. The first of these is to prevent the infective agent from entering the body at all, and in this connexion we may note that both addresses allude, though with differing emphasis, to the tonsils as the breach in the body's defences through which rheumatic infection makes its entrance. Whatever may be the final view of the place of tonsillectomy in the treatment of juvenile rheumatism, no one can dispute the urgent necessity for remembering that the tonsils are the only proved and known portal by which this infection invades the body. The second principle to be observed in all attempts to limit the injury of vital organs by infection is that an early diagnosis will be achieved more often by attention to the general than to the visceral symptoms of infection. In cardiac rheumatism some of these general symptoms are striking and unmistakable. It is both fortunate and unfortunate that the child who is attacked by this infection should suffer from articular and muscular pains; fortunate because these pains call attention to the infection in a way that cannot be ignored; unfortunate because we have grown accustomed to think of some such manifestations as essential to the diagnosis of rheumatic infection. Nothing could be more dangerous than this misconception. A large proportion, possibly a majority, of the children in whom signs of cardiac rheumatism are found have never been under treatment for articular pains or chorea, or any other overt evidence of rheumatic invasion.

How are these principles to be applied in daily practice? By no other means, we believe, than by taking trouble. If the possibility of a rheumatic origin is borne in mind in dealing with every case of vague ill health in childhood, early, careful, and repeated physical examinations will be made; and if the tenacious and obstinate character of the infection is appreciated the need for a defence as dogged and persevering will be borne in mind. The true social unit is not the factory or the school, but the family; and if children are to be safeguarded from the ravages of the rheumatic infection it is essential that every one of them, no matter of what social status, shall have the opportunity of seeing a doctor whenever necessary. In saying this we do not overlook the immense value of the work done by the school medical service; but we are sure that the school medical officers would be the first to agree that if it is to succeed the campaign against juvenile rheumatism must be carried into the child's own home.

THE DEVELOPMENT OF MEDICAL SERVICES.

THE main immediate business of the authorities to whom the administration of the Poor Law will be transferred from April 1st next must necessarily be to secure that any persons who are at that time in receipt of public assistance, in whatever form, shall continue to receive such help and relief as they are entitled to have. It is no doubt this prime concern which has resulted in the disappointing absence of declarations by local authorities, in the schemes which have been sanctioned by the Ministry of Health, that they propose, from the appointed day, to give any assistance which may be provided either by way of poor relief or by virtue of certain alternative enactments, exclusively by virtue of such enactments and not through the Poor Law. A reasonable boldness in the making of such declarations was hoped for, and the excess of caution displayed—in some cases by the local authority, and in others by the Ministry in refusing to sanction some schemes which contained such declarations—does not seem to augur well for those early steps towards the reform of health administration and the break-up of the Poor Law which are so eminently desirable. Nevertheless, the fact remains that the Local Government Act, 1929, declares "the desirability of securing" these things "as soon as circumstances permit"; and not much harm will have been done if the councils of counties and of county boroughs regard the first year of the operation of that Act as an experimental period, and if both those authorities and the Ministry of Health really endeavour during that year to settle those reforms and developments of services and distributions of function which shall become effective at its close. A proper administration of the Act not only requires a full survey of the appropriate allotment of work to various committees of the councils, and of the provision and usage of hospital and institutional accommodation, but offers an admirable opportunity for the complete overhaul of those medical services for which the authority is responsible, with a view to their co-ordination or unification, or to the improvement of the methods by which they are conducted.

In these circumstances something may well be learnt from experiments which have already been in operation. One such experiment is the Gloucestershire scheme of medical services, which is reviewed in the *Supplement* to our present issue (p. 37) by Dr. J. Middleton Martin, the medical officer of health for the county. Some account of the inception of this scheme was given in the *British Medical Journal* of February 22nd, 1919 (p. 218), and it was again referred to on July 17th, 1920 (p. 87); and, in fact, the scheme has now been in operation for some nine years—long enough to prove its advantages, and to bring out any weaknesses which may accompany them. The area and circumstances of the county of Gloucester may have afforded an unusually favourable field for some of the detailed arrangements that have been made, and it is probable that in county boroughs and in some other counties these details would have to be varied; but the aims of the scheme and the principles on which it is based may be regarded as of almost universal application. Generally the object may be said to be "to co-ordinate the work of the general practitioners, the hospitals, and the nurses in the locality for the public benefit," to develop these services "to include extended treatment for insured persons and for the sick and infirm coming within the scope of the Poor Law," and to promote research and "the practice of preventive medicine in relation to both physical and mental illness." Broadly, the methods may be described thus: (1) the division of the county into areas in which the hospitals could be grouped so that they could be brought into close relationship with one another and the opportunities they afforded to the public and the profession could be fully utilized; (2) the conducting at one centre in each area, associated if possible with a hospital, of all the medical services for which the county council was responsible; (3) the close association of the private practitioners of each area with these centres, the clinical work being done, wherever possible, by these practitioners; (4) the establishment of a medical advisory committee to the county council, to which committee should be referred all medical matters ("medical personnel of the scheme, treatment, fees, development of work, etc."); (5) the appointment of a special medical services committee of the county council, on which the chairman of the medical advisory committee is co-opted without a vote, all reports being presented through him.

This Gloucestershire model is obviously susceptible of a number of variations to suit different circumstances, but Dr. Middleton Martin claims for it in Gloucestershire a great measure of success. It is worthy just now of the closest attention, for recent and impending changes have made it of growing importance that in every locality the private medical practitioners should be made to feel that they are an essential part of public health administrative arrangements, and are used as such, and that it is part of their daily duty to take their share in the advance of preventive medicine.

PSITTACOSIS.

PSITTACOSIS is a disease of a somewhat indeterminate nature found in parrots and a variety of other birds. It has been known for a long time to those whose business brought them into contact with birds; but it was not until fifty years ago, when several outbreaks of an obscure pneumonic disease in human beings were attributed to an infection contracted from sick parrots, that the condition attracted any scientific attention. Ritter, in 1879, observed in Switzerland a number of cases of an atypical pneumonia in man, which were associated with a disease in parrots imported from Germany. Various other outbreaks were subsequently recorded. One, in Paris in 1892, attracted the attention of Nocard, who isolated from both avian and human cases a species of bacillus closely related to, if not identical with, *B. paratyphosus* B. Later workers have recovered the same organism from both sick and healthy birds, but most accepted it as the causal organism. In 1906, however, Stuzzi associated the condition with a filterable virus, and claimed that psittacosis was none other than fowl plague, a disease not uncommon in domestic poultry, but communicable to most species of birds. Cases have since then appeared sporadically in various countries. Some of these have been shown to be definitely associated with parrots; others have equally definitely had no connexion with them. In 1929, however, there was a considerable outbreak of disease in human beings in the Argentine, all associated with sick parrots. The outbreak involved several hundred human cases. Parrots from the Argentine have been exported to various countries, and in some at least of these similar outbreaks have occurred. The s.s. *Arkona* arrived in Germany in November last, and her cargo of parrots was distributed to Hamburg and Berlin. A considerable number of human beings who purchased these parrots became ill, and some of them died. Meanwhile similar outbreaks have been reported from the United

States, and the source there appears to be similar to that in Germany. Other cases have been noted from Europe, and steps have been taken to prevent the import of parrots into Germany and Switzerland as a consequence. According to the *Journal of the American Medical Association*, Surgeon-General Cumming has detailed Dr. Charles Armstrong, an epidemiologist of wide experience, to conduct a field investigation of the cases reported in the United States and to trace the source of the infection, which has been ascribed in practically every case to association with recently imported parrots. In England cases have been appearing sporadically for several years past. In our issue of August 23rd, 1924, Professor Lovell Gulland drew attention to the possible dangers of psittacosis. That same year a veterinary surgeon, his wife, and his lieutenant contracted what appears to have been this disease from a private menagerie in England. The epidemic there involved a variety of birds—parrots, cockatoos, love-birds, and finches—as well as monkeys, Tasmanian devils, and an ant-eater. A number of other cases have been recorded from Birmingham and elsewhere in the past few years. In last week's issue we published at page 197 a full report of the January meeting of the Section of Medicine of the Royal Society of Medicine, when Dr. A. P. Thomson recorded seventeen cases which had come under his notice within the past six months; and Dr. Robert Hutchison recorded twenty London cases within the last two months. While, however, these cases appear to have been due to the same infection, and to present a picture of a paratyphoid fever with pneumonic symptoms, the evidence that the disease is in fact psittacosis is still largely circumstantial. It is highly probable, but there is as yet no definite proof that it is caused by an organism acquired from parrots. There have been no cases in places such as the London Zoological Gardens, where hundreds of birds are concentrated and where fresh birds are always arriving. There have been few, if any, cases associated with laboratories where post-mortem examinations of birds are habitually carried out. It is possible, of course, that those who are always handling birds may develop an immunity to psittacosis; it is conceivable that the disease in parrots associated with this human condition *may* be coincidence, or even that parrots may have contracted the disease from human sources. The parrot, almost alone among birds, may contract human tuberculosis, and there seems no reason why it should not contract other infections from man. Our knowledge of the present outbreak is still very limited. The only conclusions to which we may come at present are, first, that there exists a human disease in this country and elsewhere which is probably associated with a disease in parrots and other birds; and secondly, that the actual cause of this condition is unknown. There appear to be no grounds for the excited apprehension which exists in certain lay quarters. If this is an instance of an animal disease transmitted to man, it is by no means the first or the most important. Every medical man knows of dozens which are as serious and much more widespread. It is certainly most important that research work, veterinary as well as human, should continue on the etiology of the conditions in both birds and men, and on their intercommunicability. It is advisable that care should be taken to avoid contamination of food and fingers with excreta from parrots—such excreta may be present on the plumage of dead birds. It is particularly desirable that parrots' beaks should not be introduced into the mouth. One would have thought that coroners investigating recent cases would have pointed the moral of close personal contact between man and his pets, but they do not appear to have seized the opportunity. It is also desirable that measures should be taken to isolate sick birds and have them properly examined; but whether it is expedient, at present at least, to impose a quarantine on imported birds is not so clear. According to present information, the incubation period may last many months, and carriers of the disease may suddenly develop symptoms after years of isolation from other birds. Until the laboratories have pronounced on the etiology of this mysterious human disease and its connexion with parrots, simple and obvious measures of personal hygiene seem to be the only precautions necessary to keep the disease in check.

THE DEVELOPMENT OF PREMATURE INFANTS.

In any out-patient department it is a very common observation that mothers will attribute all the diseases and disorders from which certain children suffer to the fact that they were premature. Of recent years several observers have endeavoured to trace a series of premature infants to see what really did happen to those that grew up, and in a recent paper[1] Dr. Sigurd Ranke describes his experience with a group of 190 such children. He bases his definition of prematurity entirely upon the weight of the baby at birth, ignoring completely the estimated duration of pregnancy in these cases. Thus only children who weighed 2,500 grams or less (approximately 5½ lb.) were considered as premature. Of these 190 children 82 have died, the majority during the first year of life, and 35 could not be traced. This left 73 children who have been re-examined and form the basis of Dr. Ranke's observations. With regard to general bodily development he finds that, while heights reach the average or exceed it, the weights tend to keep below or at the average, so that, broadly speaking, these children are relatively taller with a small weight than the corresponding normals; the general impression he has gained of them is that they are long, lean, and slim. Traces of rickets could be found in over a quarter of the cases examined, and as regards walking and speech these premature children were, as a rule, behindhand. A curious feature of Dr. Ranke's investigation is that he has formed the impression in dealing with these children that a large number of them are neuropathic subjects—actually 14 out of his series of 73; and that while training, environment, and other factors undoubtedly play their part, premature birth may perhaps also have something to do with the nervousness that such children show. On rather surer ground are his observations in regard to real mental deficiency among premature children. There is a great difference of opinion about this subject among different observers. It has long been held that the chances of development for premature children, if they survive at all, are on the whole the same as for full-time infants, and this applies also to their mental development. Unfortunately, according to Dr. Ranke's experience, the conditions cannot be regarded as so favourable, for among these children are many who in the course of their development prove to be mentally abnormal. He finds that over 5 per cent. of the survivors showed such a condition, while a further 9 out of the 73 showed a definite state of mental "backwardness." With regard to Little's disease, which is held to be relatively common among premature children, he has not been able to discover a single case among those examined. The results here summarized diverge considerably from many of the already published observations, but since the discrepancies are in both directions it would seem that there is room for further work on the subject. It is a matter of some importance, especially for the obstetrician, to know what is the likelihood, not only of survival, but of normal development, for the premature baby. The existing differences of opinion should be capable of settlement by extensive statistical studies.

THE CREATIVE PERIOD OF GREEK MEDICINE.

A RECEPTION to the members of the History of Medicine Section of the Royal Society of Medicine took place at the Wellcome Historical Medical Museum on January 30th, when Mr. L. W. G. Malcolm demonstrated some recent acquisitions, and Dr. A. P. Cawadias gave a short address on the principal currents of ancient Greek medicine. Dr. Cawadias dated the creative period in Greek medicine from the seventh century B.C. to the time of Galen (or, as he preferred to call him, Galenus), the eighteenth centenary of whose birth falls this year. He divided the period into four stages, but antedating or contemporary with the first of these was the "religious medicine" of Epidaurus, where patients went to consult the gods. Even so, Epidaurus took care to send its cases which could not be cured by suggestion to the physicians. From the seventh to the fifth century rationalizing and scientific influences began to shape Greek medicine, but Epidaurus continued its faith-healing unaffected. The first of the four periods of Greek medicine Dr. Cawadias referred to as the physiological period, when the outstanding figures among the physiologists were Thales and Anaximander of Miletus, with their vague talk of "elements" as explaining the construction of man. Based on this simple study of elements arose two schools of physicians, one represented by Pythagoras, Alemeon, and Democedes of Croton, and the other by Empedocles and Acron of Agrigentum. These physicians regarded health as the equilibrium of the elements, and disease as the disturbance of that equilibrium. This period in Greek medicine had been overlooked by those who began their studies with Hippocrates. The second period—the late fifth and the fourth century—might be called the period of clinical medicine. The physiologists were Anaxagoras, who described the humours, including the black and yellow bile, Diogenes, who conceived of the "pneuma," and Democritus, who dimly foresaw the modern atomic theory. The great schools of medicine of this period were those of Cnidos and Cos. The supposed opposition between these schools—Cos being extolled because its followers paid regard to the individual patient, and Cnidos demeaned because its followers thought only of the disease—was, said Dr. Cawadias, quite fictitious. Both schools followed the same principles of diagnosis, but Cos was ever to be associated with the fame of Hippocrates, who remained for all centuries the classic physician. The third or clinico-physiological period extended from the third century B.C. to the second century A.D. Physiologically it was dominated by Aristotle, who conceived not the vague "elements" of his forerunners, like Thales, but organs, a nervous system, the development of the embryo. Hippocrates had used physiology simply as a guiding star—indeed, it was difficult to say what were the physiological principles of Hippocrates; but by the third century B.C. it was seen that physiology must be more than a guiding star—that it must be the basis for diagnosis and treatment. The Aristotelian philosophy was worked out in the school of Alexandria, whose founders were Herophilus and Erasistratus. Dogmatic schools afterwards arose, such as the methodists of the first century B.C., with their theory of all disease as due to some simple occurrence like constriction of the pores, the pneumatists, and others. Then there were the empiricists, such as Philinus of Cos and Serapion of Alexandria. With the dogmatists everything was physiology, but with the empiricists physiology no longer existed. They said, "We can never explain what happens in the living body. Let us look simply at the symptoms." Ensuing from this there took place a reaction towards Hippocrates. Three great neo-Hippocratists of the first century A.D. were Aretaeus of Cappadocia and Rufus and Soranus of Ephesus. The fourth and last phase of the creative period was concentrated in the single name of Galenus. Dr. Cawadias refuted the notion that Galen was a Roman. The Roman conquest involved no mixture of peoples. The Romans had their governors and soldiery in many places; but, with a certain mutual contempt between Roman and Greek, there was no fusion. The Greeks maintained their purity, as they had done from the eighth century B.C. Galen was a Greek who spoke his native tongue. His physiology was something much more than the physiology of Aristotle, and he it was who introduced the experimental method whereby such enormous progress in physiology had been made. To Hippocrates and Galen medicine owed an equal debt. With the latter, however, the creative period of Greek medicine came to an end. There followed a period of compilation and transmission. The great transmitters of Greek learning were the scholars of the fifteenth century, whom the final breaking of the Eastern Empire and the passing of Constantinople into the hands of the Turks dispersed to Italy and the West. It was in the same period that a great English scholar and humanist studied Greek in Italy, became absorbed in the spirit of classical philosophy, and brought back the new learning to England, where he founded the Royal College of Physicians—Thomas Linacre.

CONTROL OF IRRADIATED PRODUCTS.

THE conflicting experimental evidence on the subject of toxic effects produced by excessive quantities of irradiated food substances is well summarized in a paper entitled "Irradiated products and public health," by Drs. F. Bordas and Jules Renault,[1] who are members of the Conseil supérieur d'Hygiène publique. Nearly all the workers, it would seem, agree that excess of irradiated substances can produce pathological effects, but here the agreement ends. Some state that the effects are due to excess of irradiated ergosterol; others blame toxic side products; some describe toxic effects which appear only when the dose is many thousand times greater than the therapeutic dose; others state that doses of the same order of magnitude as the therapeutic dose can do harm. Finally, there is wide variation in the nature of the toxic effects described. But whatever may be the contradictions in the experimental evidence—and these will obviously have to be cleared up—its general tendency leads the authors to conclude that irradiated foodstuffs should be regarded as medicinal substances which can be used safely only under skilled control. In order that the medical profession should know exactly what it is handling, they suggest that with every irradiated product sold there should be a statement about the method of irradiation that has been used, the date of manufacture, and the antirachitic potency of the product. They recommend also that irradiated products should be sold only by pharmacists, because by such means the Faculty of Pharmacists of Paris could exercise a supervision which would be effective in eliminating from the problem those added difficulties that arise from the sale of products "irradiated only on the label."

THE WINNIPEG MEETING: MOUNTAINEERING IN CANADA.

IN reply to inquiries made by British medical men as to the possibility of engaging in mountain climbing during their visit to Canada next summer, Dr. F. C. Bell, superintendent of the Vancouver General Hospital, writes that the Canadian Alpine Club, of which he is past-president, will hold its annual camp at Lake Maligne from July 28th to August 16th. Lake Maligne is one of the most beautiful mountain lakes in Canada, and at the same time one of the most inaccessible for individual climbers. Should any members of the British Medical Association attend the camp they will be well repaid for any time or expense

which may be necessary. The camp will probably be one of the best achievements of the Alpine Club. There is also a club house at Banff with very comfortable accommodation, pleasant surroundings, and an interesting library of works on Canadian travel and mountaineering. From this point there can also be arranged a great many interesting climbs, most of which could be single efforts, and would not necessarily involve so much time as the trip to Lake Maligne. Privileges of membership of the Canadian Alpine Club will be extended to members of the British Medical Association. Those unable to attend the camp at Lake Maligne, which will be held prior to the date of the Winnipeg meeting (August 26th to 29th), might visit the club house at Banff and the better-known mountains in that neighbourhood either before or after their attendance in Winnipeg. Those desiring further information may communicate with *Dr. F. C. Bell, Vancouver General* Hospital, Vancouver, B.C., or Dr. William Boyd, General Hospital, Winnipeg, Manitoba.

COSMETICS.

THE advice given by Dr. W. A. Pusey in his little book on the care of the skin and hair[1] is, as one would expect from a dermatologist of his standing, essentially sound. The chief criticism we can offer is that it is so sound that it begins to partake of the nature of platitudes. The author says he could not have written this little book without his wife; we rather suspect that his wife could have written it without him. This is not the first occasion on which a distinguished dermatologist has produced a slim volume on the care of the healthy skin. We wonder sometimes to what public they are addressed. There is nothing in them that the doctor does not know, and they are not thrilling enough for lay consumption. They do not contain the information that would be gratefully received by our profession, revealing the composition of face creams of various kinds and other secrets of the toilet. For the most part these are still the exclusive property of "beauty specialists" and pharmacists, to whom they afford a profitable field for commercial exploitation. They are hardly medical subjects, but they are full of medical interest. One group of these preparations, the hair dyes, has been well dealt with from the chemical and the technical point of view in a book lately noticed in these columns,[2] and there is undoubtedly an opening for a good treatise on the same lines on skin foods, creams, lotions, powders, and so forth. Physicians really know very little about these matters, and Dr. Pusey imparts nothing on the subject, for he gives only one formula for a glycerin skin lotion. Apparently, however, he is an enthusiast for the application of soap and water to the face. This may be all very well for the hardy male, but in our experience ladies who, with reason, are proud of their complexion have to be very cautious in the use of soap, because excess easily leads to a troublesome dermatitis, and many women of great beauty rely entirely on creams and oily preparations for cleansing the face and neck. We venture to doubt also whether he is right in suggesting that Europeans eat to greater excess than Americans, and in consequence experience earlier deterioration of the complexion. Our impression is that the American complexion is prone to coarseness at an earlier age than the British, possibly due less to overeating than to central heating. But discussion on these delicate matters, even in a medical journal, may lead to recrimination rather than finality, and is better avoided. If we may end on the same note as we began, let us conclude by saying that this little volume will be found most useful by governesses, school teachers, and others who undertake the care of the rising female generation.

PLASMOCHIN IN THE CONTROL OF MALARIA.

ADMIRABLY produced and expensively illustrated, the latest annual report of the United Fruit Company's medical department[1] is an interesting record of the practice of medicine and surgery in the tropics. We note with interest the reiteration that malaria is the major disease problem confronting the company's staff on its numerous properties, and particularly that the economic importance of malaria is being more and more grasped by plantation overseers, while the employees themselves are beginning to seek thorough treatment. Some interesting experimental work has been done with a view to applying to preventive ends the effect of plasmochin upon the gametocytes of the malaria parasite. If the experiments (p. 34) of Barber and his colleagues in the Panama division of the United Fruit Company are confirmed, it would appear that plasmochin, in doses much smaller than are used in treatment, has the power of so affecting the gametocytes that oöcysts are not formed by those ingested by mosquitos, although exflagellation occurs. The wholesale production of this effect throughout a labour force should do much to extinguish malaria. There is described what purports to be a test of the value of plasmochin as the sole preventive agent, the result of which seems to be regarded as discouraging. In our view the test was no test, since the population examined varied widely in successive surveys, and even if it had not, the method adopted—treatment of those with positive blood—was not likely to yield favourable results within the period of study. It is a pleasure to see in this report attention given to the study of tuberculosis in the tropics, which is too often forgotten by teachers of tropical medicine.

INTERNATIONAL CONGRESS ON MENTAL HYGIENE.

THE first International Congress on Mental Hygiene will be held at Washington from May 5th to 10th. In connexion with it the National Council for Mental Hygiene has undertaken to act as a liaison body in Great Britain, and the Study Tours Subcommittee of the Royal Medico-Psychological Association is organizing an expedition on the lines of its recent successful tours to the Netherlands and Paris. Attendance at the Congress is not limited to members of particular organizations or official delegates, but is open to all interested in mental hygiene. The travel arrangements are in the hands of Thomas Cook and Sons, Ltd., and special rates are available on liners leaving Southampton on April 19th, 25th, and 26th, or Liverpool on April 26th. Copies of the preliminary programme, with details of the tours and forms of application for membership, can be obtained from the secretary of the National Council for Mental Hygiene, 78, Chandos House, Palmer Street, S.W.1. The names and addresses of those deciding to participate should be sent at once to the honorary secretary of the National Council for Mental Hygiene, Dr. J. R. Lord, Horton House, Epsom. Those who are members of the Royal Medico-Psychological Association should notify also the honorary secretary of the Study Tour Subcommittee, Dr. A. Edward Evans, 3, Rotherwick Court, Golders Green, N.W.11; it will then become possible to circulate lists of names of those intending to join the congress. Early notification of travel requirements should be made to the nearest Cook's office, and all other inquiries should be addressed to Dr. J. R. Lord.

THE veteran American surgeon, Emeritus Professor William Williams Keen, M.D., LL.D., Hon. F.R.C.S., celebrated his ninety-third birthday on January 19th at his home in Philadelphia. His many friends on this side of the Atlantic will be glad to know that Professor Keen continues to enjoy good health and vigour of mind.

A MODERN ASPECT OF IMMUNITY.

HUNTERIAN LECTURE BY DR. MONOD.

A HUNTERIAN LECTURE, entitled "Immunity from a new point of view," was delivered by Dr. GUSTAVE MONOD of Paris and Vichy at a meeting of the Hunterian Society of London at the Mansion House on January 27th, with Dr. ERNEST YOUNG in the chair. Dr. Monod dealt with the subject of immunization from the standpoint of a spa physician, paying special attention, naturally, to the waters of France, with which he is familiar, but commenting on the need for further study of spas in Great Britain in order that their special merits in this respect might be disclosed.

Dr. Monod opened his address by remarking that the present generation had been trained to consider the chemical constitution of bodies, and more especially drugs, as the dominating and determining principles, but there was little doubt that the new generation would consider the matter from a wider angle. All the phenomena of life were derived, Dr. Monod argued, from chemico-physical reactions in water; it was important, therefore, that physicians should understand the modern teaching of physics with regard to molecular and electronic action, the manifestations of which were seen in diffusion, in osmotic pressure, in the reaction of colloids, and in many other forms which were not even imagined a quarter of a century ago. Immunization had been considered up to the present as merely a biological phenomenon, but he desired to show that immunity—even specific immunity—could be acquired from non-organic antigens. It had been shown experimentally that certain mineral waters, for example, had a protective action against toxic invasions, although this subject was only in the early stages of its elucidation. Châtel Guyon water neutralized the venom of the adder; St. Nectaire water acted in a similar manner against diphtherial toxin; the toxin of tetanus was checked by La Bourboule water, and there were many other examples. He would not pretend that these minerals waters had any sort of monopoly in this respect; they were an easy and cheap way of producing immunization, but other electrolytes endowed with the same property would certainly be discovered or invented. The protective or immunizing action of mineral waters, however, was a new and startling discovery, and one worthy of close attention. Mineral waters played a striking part in connexion with the phenomenon known as anaphylaxis. It had been shown that if animals were injected with horse serum, and treated for twenty-one days with Vichy water, after which treatment a second dose of horse serum was given hypodermically, they did not show the slightest reaction; this contrasted with control animals which, if not so treated, had been found to die or to become gravely ill after the second serum administration. A similar protective action was afforded by the Royat and La Bourboule waters. It was a true defensive reaction, due to the bivalent bodies of the mineral water creating around the cells an electrostatic field of protection.

The story of how the discovery of the immunizing properties of mineral waters was made was entitled to be described as romantic. In the picturesque volcanic district of the Auvergne Mountains in France a few years ago, when a shepherd was giving an outing to his flock after the long winter stabling under snow, the late Professor Billard, the pioneer in this field of investigation, happened to be in the district, and entered into conversation with the shepherd. Billard learned from him that in the early spring the animals were depressed, stupid, and so clumsy that poachers had been known to outrun a wild goat. The shepherd also told him that if bitten by a viper at this season the animals suffered no ill effects from the bite. These facts suggested to Billard that the broom on which the sheep were feeding contained sparteine—in other words, that the sheep were doped. Sparteine was known to be antagonistic to the toxin of tetanus, and Billard thought, therefore, that the antagonism might extend to snake venom, which also had a special affinity for the nerve centres. The professor tried the various mineral waters gushing up in his district, and discovered one which neutralized the sparteine with which he was experimenting.

By what means could a certain mineral water protect against a specific toxin? It might be conceived that certain toxins—that of tetanus, for example—had a special affinity for stearates; therefore, if a mineral water existed with electrolytes combined in such a way that with stearates it formed an insoluble soap, a barrier could be built by means of which the tetanic toxin was prevented from invading the neuron. It was the working hypothesis of Billard that the sensitizing action was undertaken not by proteins, but by lipoids. This was the more likely when it was considered that coagulation by heat did not hinder in any way the anaphylactic effect of antigens. One classic instance of anaphylaxis by lipoids was the celebrated case described by Weigal of a sheep merchant who developed asthma from the mere smell of crude wool. If such a hypothesis was admitted, then the part which mineral waters played became easier to understand. It was a fact experimentally ascertained that the mineral waters which dissolved soap most readily were exactly the waters which were endowed with the greatest power of desensitization against anaphylaxis. These waters introduced active electrolytes which dispersed the soaps and mobilized the lipoids more easily. If this was established, then a new class of drugs could be foreseen which acted merely by virtue of their physical properties. The production of such material had been achieved by Roger in his laboratory at La Sorbonne, and the results appeared to be quite satisfactory. The material was used externally, in the same way as an embrocation, but how it really acted was still a problem. Dr. Monod said that he would not go so far as to suggest that proteins played no part in anaphylaxis, but he thought they were controlled and determined by soaps and lipoids. It was through the latter that mineral waters played their protective part against anaphylaxis.

That mineral waters were very complex substances was not a matter for surprise when their origin was remembered. The waters which gushed up in volcanic districts were not surface waters absorbed and rejected, but synthetic waters from distillation at a very high temperature and under extreme pressure of carbonic acid gas. They came from what might be called an underground melting-pot. In other words, mineral water was a very complex solution of electrolytes, which had not yet found, when it reached the surface, its normal equilibrium. That these waters—he spoke particularly of Vichy—must be considered as a biological *milieu* there were many proofs. If an animal were bled, and the blood replaced by the same quantity of La Bourboule water, an active reaction started, and the normal ratio of haemoglobin was promptly restored. Another curious fact was that, whereas a surgical wound normally bled for twenty minutes, if the animal was treated with these waters the bleeding time was reduced to three minutes. Billard and Ferreyrolles had kept a frog muscle living and active for five days in Bourboule water.

It was an open question whether the effects of mineral waters were always beneficial; at any rate, the physician needed to be careful, for he dealt with a two-edged weapon. Billard himself wrote, "Nowadays, if I practised in a spa, it would not be without some sort of apprehension every time that I wrote out a prescription." Most spa physicians to-day had adopted what might be called the mild type of cure, as compared with the thorough-going cure of their predecessors. But why should not injections of waters be used in certain cases—before operation, for example—to prevent bleeding? Was it possible that injected mineral water might check post-vaccinal encephalitis? For the time being, no more could be done than theorize on these points. The anti-anaphylactic effect of waters might be tried on most chronic affections; it had been tested empirically, and had been successful, for centuries. As regards the waters of Great Britain, there was no doubt but that their special virtues were only waiting to be discovered. If an echo of this lecture reached the ears of British spa physicians who were endowed with pioneering enthusiasm he would feel himself well repaid.

Replying to a vote of thanks moved by Sir WILLIAM WILLCOX, Dr. MOXON added that he deprecated any idea of nationalism in science. He had spoken only of the waters of France because he knew them best. Other waters only needed to be studied in order to be utilized in the same way. One physician had told him that he could obtain the same results by getting his patient to hop three times round Trafalgar Square and sip at the fountains, to which his reply was, "Why don't you?" In conclusion, he referred to the link between professions in different countries, and said how much he was indebted to one great man of the British race, but of international sympathy—William Osler.

Scotland.

St. Andrews University.

AT the half-yearly meeting of the General Council of St. Andrews University, held on January 25th, with Principal Sir James Irvine in the chair, the question of reopening the Marine Laboratory for biological research was considered. A motion was passed suggesting that the University Court should consider the question of reopening this laboratory. It was pointed out that valuable research had been carried out, on the development and life of fishes for food, in a small cabin, which had been acquired in 1882. Between 1896, when the Gatty Marine Laboratory had been opened, and 1914, a great volume of work of a high standard had been produced under Professor M'Intosh, who had continued research work and published a book quite recently. Since the war, however, the laboratory had not been kept up. It was explained by Professor D'Arcy Thompson of the chair of zoology at St. Andrews that towards the end of last century biological research work had been of a simple nature because it was then only beginning. Now it had become very specialized, and at the other biological laboratories round the coast the services of large sea-going vessels were needed as well as staffs of experts. The cost of a research laboratory at St. Andrews that would be of national value was prohibitive, and, in any case, St. Andrews was not a suitable place for such a laboratory, so that there was little hope of getting a Government grant for the purpose of establishing one there. At the same meeting it was reported that there had been an increase of fifty students attending St. Andrews University as compared with last year.

Animal Disease Research in Edinburgh.

A meeting of the directors of the Animal Diseases Research Association was held in Edinburgh on January 29th. It was resolved to appoint Dr. John Russell Greig, professor of medicine and materia medica in the Royal (Dick) Veterinary College, Edinburgh, to be director of the institute at Moredun, Edinburgh, in succession to Mr. W. A. Pool, who has been appointed deputy director of the Imperial Bureau of Animal Health at Weybridge. Professor Greig, after graduation at the Royal (Dick) Veterinary College in 1911, engaged in post-graduate study, and was appointed to the veterinary staff of the city of Glasgow. After service in France during the war as veterinary officer to the field artillery, and later as officer in joint charge of the Royal Army Veterinary Corps Laboratory at Rouen, he returned to a post with the Ministry of Agriculture, and in 1919 was elected to a chair in the Royal (Dick) Veterinary College. During the war he investigated several war-conditioned diseases in army horses, and determined the cause of ulcerative cellulitis, which was producing heavy losses among horses in all the armies of the Western front. With Dr. E. A. Watson, chief veterinary pathologist to the Dominion of Canada, he demonstrated the fungoid organism of epizootic lymphangitis, and in 1915 introduced a method of treating wounds in horses by lymph lavage, a method which was adopted throughout the army veterinary hospitals. The important disease known as milk fever was investigated by him in collaboration with Dr. Dryerre, and for the solution of this problem he recently received the degree of Ph.D. from Edinburgh University.

Physical Welfare of Students.

The University Court of Edinburgh University has created a new post in the appointment of Colonel Ronald B. Campbell as director of the physical welfare of students from May 1st, 1930. About two years ago a committee of the University Court studied the question of physical welfare in the University, and as a result increased the matriculation fee in order to form a physical welfare fund. The committee at the same time recommended that an officer of the University should be appointed to direct the athletic activities and the physical culture of students. The appointment is not merely for the organization of games, but rather for the promotion of physical well-being in association with mental development. Colonel Campbell, after service with the Gordon Highlanders, was appointed inspector of physical training in the army, and has shown keen interest in the movement for the welfare of youth. He served in the South African war and the European war, receiving the D.S.O. for services in 1917, and being created C.B.E. in 1923.

Dunfermline and West Fife Hospital.

The annual meeting of the Dunfermline and West Fife Hospital was held on January 27th. Mr. H. M. Brownlie, who presided, said that the sums which had been subscribed towards the fund for the extension of the hospital, at present being carried out, exceeded £51,000. This amount had been raised in a period of less than two years, and under the present existing industrial conditions this was a great tribute to the generosity of the community in the hospital area. In the current year the directors would be able to provide an additional forty-four beds, as well as other new services. They had every confidence that when the extension was opened the subscribers would provide the necessary increased income to obtain efficient running of the enlarged hospital. Dr. J. Finlayson Fleming, a member of the advisory committee of the hospital, said that the extensions of the building had been well and carefully planned, and an excellent operating theatre had been provided, which he thought was one of the finest in Scotland at the present time.

Treatment of Gastric Disorders.

At a meeting of the Pharmaceutical Society of Great Britain, held in the society's hall, Edinburgh, on January 25th, a paper was read by Mr. J. Rutherford Hill on the use of calcium carbonate in treating gastric disorders. He said that in the intensive alkaline treatment of gastric and duodenal ulcers at the present time powders containing calcium carbonate were very extensively used. It should be noted that in the *British Pharmacopœia* there were two substances of this chemical composition. One was called precipitated calcium carbonate, which was crystalline in form, and, if this was used, it was liable, on account of its crystalline form, to cause much gastric irritation, and it should not therefore be used in the treatment of any gastric ailment. The other substance was known as prepared chalk, and, being amorphous, was better adapted for internal medicinal use. The language of the *British Pharmacopœia* was ambiguous as to what should be dispensed when calcium carbonate was ordered, and it was important that dispensers should supply the amorphous prepared chalk, which contained 97 per cent. of pure calcium carbonate.

England and Wales.

The Birmingham Hospitals Centre.

FOR many years past the executive board of the Birmingham Hospitals Centre has considered the question of securing a closer co-ordination of hospital facilities in Birmingham, and has devoted its activities to the preparation of a practical scheme for this purpose. In 1920, when the city was able to resume normal conditions after the war, both of the leading voluntary hospitals (the General and the Queen's) had an increasing deficiency of beds in relation to the demands that were being made upon them. These hospitals work in connexion with the medical

school of the University, and the medical staffs are closely linked up with the members of the medical faculty. About 1923 or 1924 a feeling grew up that the right solution of the hospital problem was not, as had been contemplated, to develop separate and independent extension schemes of the General and Queen's Hospitals, but to go right outside the main centre of population and build up a hospital centre where subsidiary and specialized institutions, such as eye, ear and throat, maternity clinics, and so forth, would also have free ground for expansion and be in touch with the central institutions. The advocates of a hospitals centre for Birmingham believed that even a considerable extension of the General and Queen's Hospitals would fail to meet the demands of the future, and at best would be but a temporary solution of the hospitals problem for this generation. The scientific departments of the University had already been settled at Edgbaston, and the University authorities held that as long as the two central teaching hospitals were on their present sites it was impossible to transfer the medical faculty to the University site. When Messrs. Cadbury Bros., Ltd., gave the city 150 acres of land immediately adjoining the University buildings it seemed that a practical solution of the site question might be found; it was necessary, however, to bring the two hospitals into agreement, and to this end a joint committee was formed under the chairmanship of Sir Charles Grant Robertson. This committee recommended that the new hospitals centre should be established at Edgbaston, and should be under the joint control of the General and Queen's Hospitals, and that for the satisfactory working of the scheme it was necessary that the two hospitals should be amalgamated for all purposes. These and other recommendations of the joint committee were accepted by the hospitals, and as a result an Executive Board, with Sir Charles Robertson as chairman, was set up for the purpose of making a detailed and technical scheme. This Board sent commissions to the Continent and the United States to study the most recent developments in hospital design, organization, etc., and on the basis of the reports of these commissions it framed its own scheme. In 1929, having worked out a schedule of all its requirements, it chose twelve architects to take part in a limited competition for designs of a general hospital, containing 740 beds, a paying patients' block of 100 beds, and buildings for the medical faculty. The assessor's award has now been made, the winners of the first prize being Messrs. Lanchester and Lodge of 19, Bedford Square, London, W.C.1. The Board draws special attention to the following features of the scheme.

(1) The hospital proper will represent the latest ideas and experience in the design, planning, and administration of a hospital considered simply as an institution for the treatment and cure of disease. Birmingham will have, when the scheme is completed, a hospital which, in these respects, is equal to any hospital in the world. (2) In accordance with modern needs there will be a large block for paying patients, whereby Birmingham citizens who do not come into the category of the ordinary patients of a voluntary hospital may have the advantages of hospital and institutional treatment at the lowest cost possible. The Board regards this feature as an indispensable part of its scheme, because it wishes the new hospitals centre to serve the needs of all classes of citizens. (3) There will be a close and integral connexion between the scientific departments and buildings of the medical school with those of the hospital proper. Both the Executive Board and the medical faculty agreed that there must be such an association between the laboratory worker and the clinician, not only from the point of view of the treatment of disease, but for the training of medical students and the advancement of medical knowledge.

It is estimated that the scheme will cost about £1,250,000, and to collect this amount an appeal will be launched in Birmingham in March of this year.

Small-pox in London.

The Public Health Committee of the London County Council has been considering a communication from the St. Pancras Borough Council drawing attention to the number of cases of small-pox occurring in St. Pancras and other London boroughs, and to the fact that the present procedure of tracing contacts and keeping them under observation during a long incubation period was adopted years ago when small-pox was of a severe type. As the type of disease now prevalent is extremely mild, the borough council expresses the opinion that the present procedure is not warranted, as it occupies a large amount of the time of the public health staff, and occasionally leads to loss of employment when the fact that a person is a small-pox contact is notified to the employer. In reply to the request to modify the present procedure with regard to small-pox contacts, however, the Public Health Committee of the County Council points out that it is the specific obligation of a local sanitary authority to take all necessary measures to prevent the spread of infectious illness, and that with regard to small-pox, definite duties were imposed upon sanitary authorities by the Ministry of Health in a memorandum issued in 1922 and reissued in 1926. These duties include domiciliary inquiries, supervision of contacts, action in regard to vaccination, and the taking of all necessary precautions in the homes of the patients.

"The fact that the disease happens, at present, to be associated with a negligible fatality rate can hardly be held to render unnecessary the need for taking proper precautions, especially having regard to the possibility of the occurrence, at any time, of the more toxic variety of small-pox and the difficulty of differentiation between the two types, especially when a case of the severe type is modified by vaccination carried out many years before. Furthermore, although, on the whole, the disease is mild, many cases are associated with severe illness and a copious eruption. The important factor of dislocation of businesses and workplaces through outbreaks of small-pox among employees must also be taken into account, as well as possible loss of home and foreign trade either through fear of infection or owing to restrictions imposed by the routine precautions taken."

The Ministry of Health expressed the view, in a memorandum issued in 1926, that it is unnecessary to keep small-pox contacts away from their work, subject to the necessary precautions being taken, and to their being kept under surveillance for the full incubation period. The Public Health Committee states that this practice is being followed by medical officers of health throughout London, and if a small-pox contact remains away from work it is entirely due to the action of the employers, save, possibly, in exceptional cases in which it is done on the advice of the medical officer of health. The Public Health Committee is unable to recommend the London County Council to adopt the St. Pancras suggestion, and it is stated that a reply has been sent by the Ministry of Health to a similar communication from St. Pancras, in which the Ministry states that the tracing and supervision of small-pox contacts is a routine duty of the borough council, that it is only by such means and by vaccination that the spread of the disease can be controlled, and that no relaxation of the prescribed precautionary measures can be contemplated at present.

Westminster Hospital Radium Annexe.

The Westminster Hospital Radium Annexe at Fitzjohn's Avenue, Hampstead, the opening of which was recorded in our last issue (p. 211), although an adapted private residence, is admirably fitted for its purpose. The radium "bomb" room is on the ground floor, lined with barium for the protection of workers in rooms adjacent. This room contains the apparatus devised for employing the four grams of radium entrusted to the hospital by the National Radium Commission. The apparatus is so constructed that the radium rays can be directed on two patients simultaneously, as described by Mr. Francis Rock Carling in the *Journal* this week at page 232. On the same floor there is a deep *x*-ray therapy department, containing apparatus for the irradiation with *x* rays (generated at 230,000 volts) of deep-seated malignant growths. This apparatus has been installed in accordance with the wishes of the Commission in order that the value of irradiation by *x* rays may be compared with the value of irradiation by means of the single radium unit. The *x*-ray diagnostic department is largely for localizing tumours preparatory to their treatment. Adjoining is a dark room, the walls of which, in accordance with modern practice, are painted

cream, and all work is done by reflected light. The provision for patients consists of a male ward (six beds) and a female ward (four beds) for those unable to contribute, and seven one-bed rooms, one two-bed room, and one three-bed room for paying patients, making accommodation for twenty-two patients in all. At present the second floor is allocated for nurses' accommodation, but it is hoped that donations may be provided whereby it will be possible to take an adjacent building for the nursing staff, and so set free an additional floor for patients' beds, which would add greatly to the value of the annexe. An operating theatre, with sterilizing and anaesthetic rooms, is on the first floor, and in the basement are three laboratories, respectively for pathological, for biochemical, and for physics research. The basement also contains the emanation room, with the apparatus for the preparation of radium "seeds." Here the radio-active gas, radon, is filled into small platinum shells, which are used in the same manner as needles containing the active element. All the usual administrative offices are accommodated in the building, as well as a consulting room for the medical staff, dining and sitting rooms for the nurses (there are two sisters and ten nurses), together with kitchens and larders and so forth, and in the grounds a garage to house a motor ambulance which has been presented by Hovis, Ltd. On the walls of the entrance hall of the annexe are recorded the names of 850 founders, headed by H.R.H. The Prince of Wales, who is president of the hospital.

British Dental Hospital.

The annual dinner of the British Dental Hospital (Camden Road, N.W.1) was held on January 14th, with Sir Harry Baldwin, president of the hospital, in the chair. Sir Thomas Oliver, proposing the toast of "The Hospital," emphasized the importance of toxins generated by micro-organisms in the mouth or of gastro-intestinal origin in causing physical inefficiency among workers in factories, and in preventing industrial life from being as health-promoting as it otherwise might be. He described the steps that had been taken to prevent various industrial conditions from causing ill health, and urged that, in addition to the medical examinations of the mouths of candidates for work in lead factories, there should be a further examination a few months later. The value of school dental clinics was undeniable, but, unfortunately, the subsequent period of life was unguarded by any definite arrangements for supervision of the teeth. Dental clinics in factories would undoubtedly have an economic value, but the provision of such benefits had definite limits. Sir Thomas Oliver commended the British Dental Hospital in that, while they treated the necessitous poor gratuitously, they recognized that many patients were willing to make some financial return for the benefits received. He thought that employers in large industrial firms could render valuable services to their employees by subscribing to dental hospitals, thereby securing for the workers any treatment they might require. He welcomed the opportunity of supporting the British Dental Hospital in its effort to secure the necessary extension of its buildings, and to bring its scientific equipment up to date. Sir Harry Baldwin, replying to the toast of "The President," mentioned the urgent need of funds to enlarge the premises or to undertake other building operations. The large number of patients made better accommodation imperative.

Association of Clinical Pathologists.

The third annual meeting of the British Pathologists' Association was held in the Pathological Department, University College Hospital Medical School, London, on January 25th. At the general meeting it was decided to change the name of the association to the Association of Clinical Pathologists. The morning session was devoted to the consideration of the technique and interpretation of the fractional test meal. Communications were made by Dr. Emma Pillman-Williams, who described the technique of the withdrawal and analysis of the meal, and by Dr. G. W. Goodhart, who dealt at length with the interpretation of results. Dr. Goodhart laid special stress upon the importance of the determination of the chlorides, and expressed the opinion that the findings could best be accounted for on the assumption of regurgitation of alkaline duodenal contents. Both papers were followed by lively and informative discussion. During the afternoon session demonstrations were given as follows:—Dr. H. D. Wright: Medium for growing pneumococci; Haemolytic power of streptococci. Dr. G. W. Goodhart: Diphtheria of the vulva; Pernicious anaemia without achlorhydria. Dr. D. Embleton: Blood from recovered case of agranulocytic angina. Dr. G. W. Barnard: Hearts injected to show the coronary circulation; Hearts showing coronary thrombosis. Professor Hadfield: Specimens from case of Lindau's disease and other pathological specimens.

France.

[FROM OUR OWN CORRESPONDENT.]

"1930."

THIS year will mark a turning-point in our professional history. For many years we answered only with a sceptical smile when the wild prophets spoke of a possible law, "les assurances sociales," insuring the French working class against practically every risk they could run. This is first of all a political question, and as such it does not come within the scope of the medical profession. But as the health insurance law is one of the most important parts of the general scheme, and as it cannot be enforced without the agreement of the medical profession as a whole, the problem has now reached an acute stage. The Government has made a declaration that the law shall be enacted this month. But, as I have mentioned before in these columns, as soon as we realized the danger of being turned into a flock of State doctors, our hands tied behind our backs with red tape, the whole profession found out that salvation meant unity, and all our dissensions were put away. A confederation of all our professional local syndicates was created, with Professor Balthazar in the chair, uniting about 12,000 practitioners. Every one of them sent a special subscription to provide for a war fund, and signed an agreement declaring they would not accept any individual proposition from the administration. The result proved to be immediate. The principal points to which we object in the law have been withdrawn, and as we never objected to the principle of the law, but to its mode of application, we can congratulate ourselves on the first innings. But the Ides of March are pretty near. The modifications which have been granted to us must be sanctioned by Parliament. We trust they will be: if not there will be a law in France providing for insurance against sickness which will have to be put into force without the collaboration of the only people who could make it effective. Thanks to the campaign that has been started in the press, the public begins to understand that the medical profession is not fighting for any personal advantage. It is easy enough to make the man in the street recognize that it is his right and privilege to choose his own doctor, and that it is a question of personal dignity that his various ailments, with diagnosis, treatment, and history of the case, should not be entered up in plain language on the files of the administration. "Libre choix et secret professionnel"—that is our platform. It seems very likely that the law, which was passed rather hastily by Parliament, will be largely amended for the benefit of the public; and, in any case, even if the medical profession fails to carry through the whole of its programme, we shall have realized unity in our ranks and earned the right to call ourselves, as we do, confrères.

A New Faculty?

Anyone who has visited the Paris Faculté de Médecine must have walked out with a feeling of cramp. It is a terrible experience to have to grow without expanding. And such has been the case with our Alma Mater. Very few of our visitors realize what an amount of courage and will power some of our teachers must possess to work under the existing laboratory conditions. No doubt it is difficult to provide for the student from abroad when space is so much restricted for our own students. The fact

cannot be concealed—very fortunately, as it happens—for it struck the attention of the Rockefeller Foundation, which has made a generous offer of six million dollars for reconstruction, on condition that the City Council gives the ground where the wine market is now located, and that the State subscribes the same amount of money as the Rockefeller Foundation offers. It is easy to imagine the enthusiasm such a plan has aroused, to say nothing of the deep sense of gratitude. It was a similar gift, under similar conditions, that allowed the city of Lyons to construct a new medical school, and it is to be trusted that the official world will find its way through a labyrinth of difficulties.

Georges Clemenceau, M.D.

Dr. Roux, the director of the Pasteur Institute, recently read a paper on the most famous, and least conspicuous, member of the Académie de Médecine—Georges Clemenceau. "The Tiger" was elected a member in 1918, and at the same time he became a member of the Académie Française. He behaved to both bodies alike, and never attended a meeting, much to the surprise and to the indignation of those who might have thought that they had done him some honour. The Grand Old Man was too grand and too old. He had long forgotten that he had ever been a medical man or a literary man. All his interest was now in personal meditation, and he devoted the small hours of the day to philosophy and the study of religions. Dr. Roux told his audience the now well-known story of Clemenceau's medical career, and it was interesting to learn from the beloved disciple of Pasteur that the only scientific paper Clemenceau ever wrote was to advocate the cause of spontaneous generation, which was to be attacked by Pasteur a few years later. But young Clemenceau stood by the side of Robin. Perhaps the fact that he represented a fourth generation of doctors made him more of a traditionalist in science than he proved to be in politics. He graduated in 1865, and left for the United States, where he taught French to young ladies. Perhaps he forgot medicine, but at any rate he acquired a strong and lasting knowledge of English, which may have been the reason of his devotion to political international policy. In 1871 Dr. Clemenceau started a private dispensary in Montmartre, showing great interest in the social side of medicine, and becoming a strong advocate of breast-feeding, but very soon he was elected mayor of his district and his public life began. From his medical training he derived his constant interest in hygiene and in all scientific questions, and his last writings dealing with philosophy show throughout a biological basis. Dr. Roux concluded his eulogium by stating that, although Clemenceau never attended the meetings of the Académie de Médecine, his seat never looked empty, as in heart and spirit they always felt his presence amongst them. One word more. We may speculate wildly about what might have happened if young Dr. Clemenceau had shown more enthusiasm towards what he might have thought to be his real vocation. But France would have lost her statesman. Possibly she might have gained a great physician, though I have my doubts. "The Tiger," as his public life showed, was more inclined towards the call of surgery.

G. MONOD.

Correspondence.

COLITIS.

SIR,—I read with much interest Dr. Letheby Tidy's paper on this subject, published in the *Journal* on January 25th. It is an important and instructive contribution to a difficult subject. There are just two points in connexion with the question of diagnosis which I think merit further comment.

Dr. Tidy deprecates the use of the sigmoidoscope, and discourages investigation by means of the barium enema and meal. I would like to associate myself with Mr. Lockhart-Mummery (February 1st) when he takes exception to the statement that "sigmoidoscopy gives no useful information," may do definite harm, and should never be employed." The lack of early recognition of cancers of the rectum, recto-sigmoid, and pelvic colon is notorious. The surest way to avoid mistakes is by the routine use of the sigmoidoscope. Furthermore, the instrument can be employed with safety by the practitioner if a few elementary precautions are observed. Dr. Tidy thinks that serious results may follow such examination in catarrhal inflammations, but I have never seen a patient suffer afterwards when it is properly carried out.

Dr. Tidy also suggests that radiograms may be relied upon almost absolutely to establish the presence or absence of a neoplasm of the colon, but that in cases of colitis the barium meal and enema may occasionally be definitely injurious. In my experience early growths are frequently missed, even in the hands of the most expert radiologists. I have never seen a patient suffering from colitis injured by a barium enema or meal.

Although Dr. Tidy obviously refers to cases in which the diagnosis presents little difficulty, there are others in which uncertainty prevails. In this latter group delay or error may be fatal. On the whole, the advantages gained by sigmoidoscopical and radiographical examinations so outweigh any possible disadvantages that they should be employed as a routine.—I am, etc.,

Dublin, Feb. 2nd. W. I. DE C. WHEELER.

SIR,—There can be few diseases in which one method of treatment is absolutely right and all variations from it are absolutely wrong. I gather that the results of treatment of ulcerative colitis by the methods of Mr. Lockhart-Mummery, the Guy's physicians, and those described in my article are all far better than the appalling mortalities often recorded, especially by "medical treatment." "There are nine and sixty ways of constructing tribal lays, and every single one of them is right," but there must be some common basis. I believe that the essential factor is the feeding. A case of ulcerative colitis which is starved has scarcely a ghostly chance; with proper feeding the colon, *ipso facto*, has its opportunity. I know that Mr. Lockhart-Mummery agrees as to its importance. He has criticized some small points in my diet: I would accept his suggestions without hesitation for a patient under proper observation.

There are two special points on which the writers in the *British Medical Journal* have disagreed with my article. The writer of your editorial comment retains an affection for antidysenteric serum. Undoubtedly some dramatic cures were recorded when it was first employed. This is a common phenomenon. "Let us hasten to drink these waters," said Trousseau, "while they still continue to cure." I am afraid that the day of this treatment has passed, though, no doubt, from time to time remarkable results will be published.

The question of sigmoidoscopy is of greater importance. Both Mr. Lockhart-Mummery and the writer of the editorial have, in my opinion, missed the point where it does harm—namely, in the passage into the rectum. The passage of a speculum is equally to be deprecated, digital examination should be reduced to a minimum or avoided altogether, and an enema nozzle should never be employed. The arguments given for its use still leave one unimpressed. The writer of your editorial considers that it enables one to judge when "the mucous membrane has regained its normal aspect," and that the treatment must be continued until this has occurred. I have no hesitation in saying that the mucous membrane in ulcerative colitis never regains its normal aspect. Anyone who expects to find this with a sigmoidoscope must have made some mistakes in observation. This is so evident that I think the statement must have been penned in haste, but it is given as the principal argument for sigmoidoscopy.

Mr. Lockhart-Mummery refers to the diagnosis of cancer, in which he has, admittedly, a very large experience. He mentions especially the difficulty of diagnosing a small early carcinoma. Of course this is so. The point is that a small early carcinoma below the splenic flexure does not

reproduce the symptomatology of ulcerative colitis. I have given the distinctive features in my article. When the possibility of ulcerative colitis has been thus excluded, sigmoidoscopy may be used to diagnose carcinoma from other conditions. It is this mistaken argument which has been used as the strongest support for sigmoidoscopy. The other arguments for the use of sigmoidoscopy all deal with very rare conditions—for example, primary tuberculosis of the intestine or amoebic dysentery in persons who have never been out of England and who pass no amoebic cysts.

The writer of your editorial mentions that at Guy's Hospital medicated enemata are given from the onset, but that albargin was found too irritating. Certainly this would be so. It is almost fatal to employ albargin at the beginning. At such stages saline is preferable even to tannic acid.—I am, etc.,

London, W.1, Feb. 3rd. H. LETHEBY TIDY.

ETIOLOGY OF GALL-BLADDER INFECTIONS.

SIR,—In Professor Wilkie's interesting and valuable address on the *etiology of gall-bladder infections* at the Medical Society of London, reported in the *Journal* of February 1st (p. 196), reference is made to some early experiments by myself, which were described in the Address in Surgery to the British Medical Association in 1905. In these experiments indigo particles introduced into the duodenum were subsequently recovered from the gall-bladder in several cases of fistula following cholecystotomy. This suggested to me the occurrence of a reverse current or flow of mucus (and other materials) along the common and cystic biliary ducts from duodenum to gall-bladder. From similar observations on the urinary system in cases of ureteral and kidney fistula, the suggestion was also made that, among the predisposing conditions which may lead to these reversed mucous currents, one of the most important was stasis leading to regurgitation at some point in the tubular system or the mucous canals concerned.

There is one fact about the function of the gall-bladder, established by Continental observers, and not alluded to in Professor Wilkie's address, which has an important bearing on this theory of a backward mucous current as a factor in the production of local infections. I refer to the capacity of the mucous membrane lining the gall-bladder to absorb water, by which a considerable degree of concentration of the contained bile is brought about. Now this reduction of volume and tension in the contents of the gall-bladder, so produced, may become a powerful agent in causing stasis or even a backward flow along the ducts; and, while I fully admit the possibility that organisms may reach the gall-bladder in some cases by descent from the hepatic duct, in others by the blood stream or by the lymph stream, I still think that ascending infection takes place from the duodenum by way of the common and cystic ducts in a number of cases.—I am, etc.,

Leicester, Feb. 3rd. C. J. BOND.

ANTIMALARIAL MEASURES.

SIR,—In your issue of February 1st (p. 207), commenting on the report of Colonel S. P. James *on antimalarial* measures in Kenya and Uganda, there occurs the following:

> "The third factor, brought out in detailing the duties of the special staff proposed for this work, is that the modern practice regarding actual measures *employed in attacking the malaria* problem differs from that employed up to the early war years. Those who have been in constant touch with malarial matters will find little that is novel in much that Colonel James has to say on these points: how it is no longer thought necessary always and in all circumstances *to base antimalarial measures on* knowledge of the malaria-mosquito cycle; how malaria is a social disease; how diet, housing, economic status, general sanitation, and other factors play a part."

As one who has been in constant touch with malarial matters during the past twenty-nine years, I should like to point out that my experience of malaria in the tropics has led me to conclusions directly opposite to those of Colonel James. My experience is that malaria is not a social disease; that diet, housing, economic status, and general sanitation are factors that play a practically negligible part in the spread of malaria in intensely malarial regions in the tropics.

In Malaya nothing was more striking than how malaria struck the best-educated and the best-fed people, living under the best sanitary conditions, if their houses were close to the breeding places of the species of anopheles which carried the disease; while the ignorant, poorly housed and poorly fed entirely escaped if they lived only half a mile from such *breeding places*. An ever-increasing knowledge of the malaria-mosquito cycle acquired, *not less by unremitting practical work than by research*, has enabled malaria to be controlled over ever-widening areas in Malaya. Control has spread from small towns to large towns, to estates, mines, private undertakings and public works, villages and many rural areas, and a great organization was created in 1926 to cover the whole country.

Already there has been a saving of tens of thousands of lives (over 58,000 in the city of Singapore alone since 1911), and an enormous, indeed incalculable, saving of money. Two examples of the latter must suffice. At the recent opening of the new water supply for Singapore the president said the antimalarial work had saved the commissioners "at least one million dollars (£120,000) in the construction"; and the commissioners showed their appreciation of Dr. Hunter's work by voting him a bonus of 25,000 dollars, equal to nearly £3,000. (Other councils please note.) The consulting engineer's representative on another work assured me that the antimalarial measures had resulted in a saving (in wages, coal bill, and loss of profit and interest on capital) to the company of over £26,000 a month.

There are sound reasons for believing that malarial control, based on a knowledge of the malaria-mosquito cycle, could be used successfully even in many poverty-stricken villages in countries outside Malaya, where the present attitude of the authorities is that malaria is an insoluble problem. I am afraid, however, that these villages must wait until they get the type of man described recently by one of our greatest scientists: "There is a certain type of man who is badly wanted at the moment. This is the scientific man who can administer; the administrative man who knows science. . . . We have men who can explore in the laboratory, but we have not enough men who can take what is discovered into the world. . . . We want people who are not merely scientists, we want people willing to take responsibility."

Judging from a recent communication by Colonel James to the Royal Society of Medicine, the best advice he can offer to the people of the great malaria-stricken tracts of the earth is to improve their houses and economic position and to wait patiently until they have acquired such a racial immunity to the disease that it will no longer sicken and kill them as it does now. Those who have seen native races acquiring partial immunity (and it is never *more than partial*) are aware of the appalling loss of life that occurs among both children and adults during the process, throughout which they are a danger to themselves and others who visit them, and possibly always in danger from infection by a new strain of parasites.

My observations in many tropical lands lead me to believe that hundreds, probably thousands, of years must elapse before any considerable amount of racial immunity is acquired. An example of it can be seen among the aboriginal tribes of India, who have been driven by successive conquerors into isolated hill tracts like the Jeypore Agency of Madras. The adult inhabitants of this region have certainly acquired a comparatively high degree of immunity. But it is dangerous in the extreme for any non-immune person to visit them; and the record of both Indians and Europeans who attempt to live in an administrative centre like Koraput in the Agency is one of intense malaria, constant invaliding, blackwater fever, and, too often, death. Forty years ago the Malay Peninsula had a similar record. Sir Hugh Clifford, the late Governor of Malaya, whose forty-seven years of administrative work included service in the West Indies, Gold Coast, Nigeria, Ceylon, and Malaya, described the Malay Peninsula as having been "by far the most malarious tropical country with which I have any personal experience," and he added that "it must be quite obvious to all that its great development would have been totally impossible unless the danger of malarial infection had first been successfully combated."

ANAESTHESIA FOR SHORT OPERATIONS ON CHILDREN.

SIR,—In the *Journal* of January 25th (p. 147) Dr. Marcus Bird gave an interesting account of his revival of the use of oxygen with ethyl chloride as a general anaesthetic for operations of short duration. This combination was tried at the Central London Throat Hospital in 1908. Given early in the inhalation oxygen seemed to excite the patient and prolong the period of induction; given towards the end of the inhalation it seemed to be rather useful in promoting a long and quiet anaesthesia. Even without oxygen, ethyl chloride has been given at that hospital to many thousands of children (seated in chairs) without cyanosis or syncope; the preservation of a good colour in the vast majority of cases having, indeed, been rather remarkable, the more so in view of the unavoidable haemorrhage from the upper air passages.

Dr. Bird seems to use rather large doses for children over 8 years old, but I believe, and I dare say he will agree, that removal of the mask at the right moment is a good deal more important than meticulous accuracy of dosage. Of 11,723 patients subjected to ethyl chloride at the Central London Hospital before 1908, only about three required formal artificial respiration, and they all recovered. Oxygen given scientifically, as Dr. Bird suggests, with ethyl chloride will probably prove of great value whenever a little loss of time is of no importance.—I am, etc.,

BERESFORD KINGSFORD, M.D.,
January 28th. Consulting Anaesthetist, University College Hospital.

SIR,—I was interested to see that Dr. Harold Sington has emphasized the safety of ethyl chloride given to children by the usual open and closed methods without the use of oxygen. During the last ten years at the Queen's Hospital for Children over 30,000 cases have been anaesthetized with closed ethyl chloride for dental extractions. So far as I am aware there has been no serious difficulty at the time, or afterwards, with any of these patients. Thus, with the series of 40,000 administrations at Great Ormond Street Hospital, we arrive at the very respectable total of 70,000 consecutive anaesthesias without ill effects. —I am, etc.,

C. LANGTON HEWER,
Senior Anaesthetist, Queen's Hospital for
London, N.W.1, Feb. 1st. Children.

TONSILLECTOMY OR RADIOTHERAPY.

SIR,—In support of Dr. Douglas Webster's letter in the *Journal* of February 1st (p. 216), I wish to add my testimony as to the value of *x*-ray treatment in cases of enlarged chronically inflamed and septic tonsils. I have employed this method of treatment in preference to operation during the past eighteen years, with eminently satisfactory results.

Dr. Webster is certainly correct in saying that the tonsil is one of the most radio-sensitive parts of the body, as is evidenced by its rapid response to a few small doses of *x* rays suitably filtered. The process is painless and rapid, and requires neither the administration of an anaesthetic nor after-treatment in any shape or form, and it is quite free from danger. I also agree with Dr. Webster that small doses are preferable to large ones, and that the softer rays should be excluded, but, of course, each case must be treated upon its individual merits with regard to quantity and quality of the rays administered for each dose; there is also a fairly wide range in the number of doses required, some tonsils reacting more rapidly than others; the interval, too, between the sittings must be determined by result obtained, but that is a matter which comes by experience.

The *x*-ray treatment is by no means confined to children; some of the most satisfactory results are obtained in adults with chronic septic tonsils of many years' duration; and therein, in my opinion, lies the special value of *x*-ray treatment, because it is in these adult cases that there is special danger to the patient during the operation of tonsillectomy, and often a painful and prolonged period of after-care.—I am, etc.,

London, W., Feb. 1st. CHRISTOPHER KEMPSTER.

POISONING BY HYDROCYANIC ACID GAS.

SIR,—It was with great interest that I read the report of a death from hydrocyanic acid gas poisoning on page 152 of the *British Medical Journal* of January 18th, and a further reference to the same case in your issue of January 25th.

During the war I was engaged for some time on a plant manufacturing hydrocyanic acid gas. On two occasions I had the misfortune to be "gassed." The sensation was curious. It felt as if someone of Carnera physique, wearing outsize boxing gloves, had hit me on the face and chest, then oblivion. The treatment consisted of large doses of sal volatile, and then three men ran me up and down the parade ground for about fifteen minutes.

I am not surprised that traces of HCN were found in the lungs, as I could distinctly feel the taste in my mouth twenty-four hours after the accident, though I suffered no after-effects.—I am, etc.,

JOHN R. GRAHAM,
January 31st. Deputy Medical Officer of Health, Oldham.

THE NATURE OF "PSYCHOGENIC PAIN."

SIR,—Dr. Walshe's letter (January 18th, p. 126) raises an interesting question, which can hardly be passed without criticism.

Are there two kinds of pain having different "natures"? When we experience any sensation the end organs of sensory nerves are stimulated and nerve impulses are carried to central neurone groups. Whatever these neurone groups are specialized for determines the nature of the sensation which arises in consciousness. These sensations arise in what is the domain of the psyche; they are psychical, but their origin is physiogenic. After these central neurones have been stimulated on one or more occasions, and have become associated with other groups, it is possible to rouse the memory of such stimulations in thought (psychogenically) without again experiencing a fresh sensation from the end organs (physiogenically).

When one recalls a sensation it is usually supposed that the same central nerve elements are concerned as were stimulated when the original sensation was experienced. When we think of a sensation, say of "red," we are raising in consciousness the previous sensations of "red." We produce psychogenically what was orginally physiogenic. We may, of course, only *think* about "red," as Dr. Walshe says we do about pain, but we do more than that; we recall what "red" appears to be. The difference in normal individuals between recalling a sensation and actually experiencing it is probably one of degree only; some can recall past sensations so vividly that they may have nearly the same intensity as a new experience. In abnormal states of the brain we see analogous conditions. In fevers, alcoholic poisoning, etc., the patient may raise in memory scenes so vivid, and combine them in such a way, that they become hallucinations—that is, the scenes and events are, in the consciousness of the patient, appearing and taking place before his eyes.

Pain differs very little from other sensations as regards the points I have referred to. Happily it is perhaps more difficult for normal individuals to recall pain in its intensity than to recall many other sensations. To my mind there is no doubt that in many persons, and especially those suffering from some functional neuroses, sensations of pain can arise and can be intensified psychogenically. They do not just think *about* pain, they think pain—that is, the pain is raised psychogenically. In physiological terms the neurone patterns concerned in the pain are stimulated by the neurone groups or patterns concerned in the thought.

One can, in an analogous way, explain the pains raised and cured by suggestion, or the disappearance of pain when the patient reaches the dentist's door. I see no reason why the pain which has a psychogenic origin should be different in "nature" from the pain having a physiogenic origin, any more than the colour red which we think of should be of a different "nature" from the colour red which we see before us.—I am, etc.,

WILLIAM ELDER, M.D.
Leith, Jan. 23rd.

AN OPTICAL ILLUSION.

SIR,—The following is possibly the most remarkable optical illusion that has yet been discovered, and very few fail to see it with ease.

Take a piece of black cardboard eight inches square, and place it on a wallpaper with a coloured pattern. The light in the room should not be too bright, but the experiment can be done easily in the daylight of the present time. The cardboard should be looked at with one eye at a distance of six feet, the eye being kept as immovable as possible. It will then be noticed that portions of the colours of the wallpaper will appear to detach themselves from the wallpaper and move with a slow spiral motion into the black area. This will go on until the whole black area has completely disappeared, the surface being covered with a mixture of colours similar to those on the wallpaper.

If a Persian carpet be used for the purpose of the experiment the area will be covered with a mixture of the colours of the carpet. If the background is of a uniform colour the black area will be covered by that colour. It may even make another colour disappear. For example, if a piece of red paper an inch and a half square is placed on a piece of yellow-green cardboard, the yellow-green will appear to invade the red until only a yellow-green surface is seen. If any difficulty is experienced the experiment should be tried in a dimmer light.

This experiment was deduced from my theory of vision—namely, that the cones of the retina are the percipient elements and the rods of the retina are the nervous elements which sensitize by means of the visual purple the liquid surrounding the cones, and are not themselves percipient elements. The central portion of the retina, the fovea, corresponding to the area of most acute vision, contains only cones, and therefore is sensitized from the periphery, there being a steady flow of sensitized liquid into this area.—I am, etc.,

Board of Trade, S.W., Jan. 22nd. F. W. EDRIDGE-GREEN.

Obituary.

DR. PHILIP HEDGELAND ROSS, who died last year while on a visit to England, was the first director of laboratories in the British East African Protectorate. He was born in New Zealand in 1876, and received his medical education at the University of Otago and at St. Bartholomew's Hospital. He obtained the diplomas M.R.C.S., L.R.C.P. in 1900, and the D.P.H.Cambridge two years later. In 1903 he was appointed to the East African Medical Service, and subsequently became Government bacteriologist to the East African and Uganda Protectorates, where he rendered most valuable services in combating epidemic diseases such as plague, and in research work relating to the transmission of trypanosomiasis and African relapsing fever. In March, 1916, he became honorary adviser to the Director of Medical Services in East Africa, and at Nairobi reduced the death rate from bacterial dysentery by means of a carbolized polyvalent vaccine which he prepared. Owing to failing health he was invalided out of the East African Service and returned to New Zealand in 1919. He published a large number of articles in various medical journals relating especially to vaccine therapy and tropical diseases. Dr. Ross was a member of the British Medical Association. He leaves a widow and one son.

DR. JOHN HOWIE SMITH, who died on January 8th, was born in 1857, and received his medical education in Edinburgh, where he graduated M.B., C.M. in 1888. He had practised in Stockport for more than forty years, holding the appointments of medical officer to the Union Workhouse and Stepping Hill Poor Law Hospital, district medical officer and public vaccinator, and medical officer to the Cottage Homes. He had completed the full term of twenty-five years as an honorary surgeon to the Stockport Infirmary. J. T. B. writes: Dr. Smith possessed ability, wide experience, and sound judgement, and was always ready and willing to advise or assist a colleague. He was a man of the highest professional integrity, and was deservedly one of the most popular and most highly respected members of the medical profession in the district. He took a great interest in all kinds of outdoor sport, and in his younger days he was a footballer, and latterly a golfer, of no mean ability. Dr. Smith will be affectionately remembered by a large circle of patients and friends.

We regret to announce the death, on January 1st, in Cairo, of Dr. C. FLOYD HAVILAND, superintendent of the Manhattan State Hospital, Ward's Island, New York. Dr. Haviland had a distinguished career in psychiatry. He was formerly State Commissioner in Mental Hygiene, and in 1926 president of the American Psychiatric Association. The news of his unexpected death at the age of 54 came as a shock to his American colleagues, and to a still greater number of other friends and admirers.

The death occurred, on January 22nd, of Dr. JOHN CROMIE, Auchencairn, Castle Douglas. Born in the North of Ireland in 1855, he studied medicine at Belfast and Newcastle-on-Tyne, and obtained the diplomas L.R.C.P., L.R.C.S. Edinburgh in 1885. For a time he acted as assistant to the late Dr. Trotter at Blyth, Northumberland, and afterwards conducted an extensive practice at Auchencairn. He took a great interest in the public affairs of the Stewartry, serving for many years on the education authority for Kirkcudbrightshire, of which he was vice-chairman at the time of his death. He had recently been elected to the Stewartry County Council; he was chairman of the National Health Insurance Committee, secretary to the local branch of the British Red Cross Society, and a Justice of the Peace for the county. He rendered valuable services to the British Medical Association, being secretary of the Dumfries and Galloway Division from 1923 to 1928, and chairman from May, 1929. He was a member of the Scottish Committee in 1924–25.

DR. WILLIAM EIDINOW died from heart failure at the early age of 34, on January 23rd, at Hampstead. After studying medicine at the London Hospital he obtained the diplomas of M.R.C.S., L.R.C.P. in 1917, and held the appointments of emergency officer and surgical clinical assistant. He served during the war from 1917 to 1920 as captain in the R.A.M.C. in France, Italy, and Montenegro, and was awarded the Italian silver medal for valour for conspicuous bravery in the field. After demobilization he took up a busy practice among the working classes of Islington, where he was much esteemed and appreciated by all who knew him. Much sympathy is felt for his relations in their great loss.

News has reached this country of the death of Dr. DARWIN MILLS KEITH, who practised for more than thirty-five years in Rockford, Illinois. Darwin Keith was born in 1855, and his early education was received in Ohio and New York; he later attended the Universities of Michigan and Columbia, and subsequently studied at St. Bartholomew's Hospital, London, and the University of Brussels. He obtained the diplomas M.R.C.S., L.R.C.P. in 1906, and the M.D.Brux. degree. After graduation, and while he was practising in Rockford, he frequently engaged in post-graduate work in London, Vienna, Paris, Brussels, and Copenhagen, specializing in diseases of the eye, ear, nose, and throat. At one time he was clinical assistant in the throat department at St. Bartholomew's Hospital. Dr. Keith was a Fellow of the American College of Surgeons, a member of the American Academy of Oto-laryngology and Ophthalmology, and of the American Medical Association. During the war he served with the American Forces with the rank of captain, and subsequently held a commission as major in the Medical Reserve Corps until his death. He was head of the medical staff of the Rockford Eye, Ear, Nose and Throat Hospital. He had many friends in England and on the Continent. He leaves a widow and one daughter.

The following well-known foreign medical men have recently died: Professor DANIEL SABOLOTNIJ, president of the Ukrainian Academy of Sciences, and one of the most eminent Russian bacteriologists; Dr. FRANK STADLER, formerly director of the Austrian Public Health Office,

aged 68; Geh. Med. Rat Dr. WALTER OERTEL, who took an active part in the campaign against tuberculosis; Dr. D. IONESCO, professor of clinical medicine at Bucarest, well known for his work on angina pectoris, aged 53; Dr. VIALLETON, professor of histology and embryology at Montpellier; Dr. N. VAN RIJNBERK, an eminent Amsterdam ophthalmologist, aged 84; Dr. RÓMULO H. CHIAFFONI, a Buenos Aires neurologist; Dr. HARRY MONROE MCCLANAHAN, emeritus professor of paediatrics, University of Nebraska College of Medicine, aged 72; Dr. VICTOR CLARENCE VAUGHAN, formerly dean of the medical school and professor of hygiene at Michigan University; Dr. PAUL HEIM, professor of children's diseases at Budapest, and one of the editors of *Archiv für Kinderheilkunde*; Dr. CARLOS SEIDL, professor of public health at Rio de Janeiro, and formerly director of public health in Brazil; and Dr. ANTONIO JOSÉ D'ALMEIDA, formerly President of the Republic of Portugal.

Universities and Colleges.

UNIVERSITY OF LONDON.

UNIVERSITY COLLEGE.

A COURSE of six public lectures on antiseptics will be given in the department of pharmacology, University College, Gower Street, W.C.1, by Mr. H. R. Ing, M.A., D.Phil., on Mondays and Thursdays at 5.15 p.m., commencing on February 13th. The lectures are open, without fee, to students of the University and others interested in the subject.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN ordinary comitia of the Royal College of Physicians of London was held on January 30th, when Sir John Rose Bradford, the President, was in the chair.

Mackenzie Mackinnon Research Fellowship.

The President announced that the Mackenzie Mackinnon Research Committee had elected Dr. G. Scott Williamson and Dr. Thomas Cecil Hunt to Mackenzie Mackinnon Research Fellowships.

Appointment of Representatives.

Sir John Rose Bradford was appointed to represent the College at the ceremonies of inauguration of the University buildings presented by the C. R. B. Educational Foundation and of the School of Medicine presented by the Rockefeller Foundation, to be held at Brussels in June next. Dr. S. A. Monckton Copeman was appointed delegate to the congress of the Royal Sanitary Institute to be held at Margate in June next.

Diploma in Gynaecology and Obstetrics.

The College adopted the regulations drawn up by the Committee of Management of the Conjoint Board for the institution of a Diploma in Gynaecology and Obstetrics.

Anaesthetics in Confinements.

In response to a request from the Ministry of Health for the views of the College on the use of anaesthetics in confinements and on the subject of maternal mortality and morbidity, reports on these subjects were considered and adopted for presentation to the Ministry.

Membership.

Dr. J. W. Springthorpe, who resigned his Membership in 1919, was re-elected a Member of the College.

The following candidates, having satisfied the Censors' Board, were admitted Members of the College:

John Bevan-Jones, M.D.Lond., Arnold Clark, L.R.C.P., Reginald Charles Clifford, D.S.O., M.C., L.R.C.P., Cuthbert Leslie Cope, M.B.Oxf., Gordon Cripwell Dewes, L.R.C.P., Hugh Alexander Dunlop, M.B.Lond., Florence Mary Edmonds, M.D.Lond., John St. Clair Elkington, M.B.Camb., Leonard Findlay, M.D.Glas., Saradindu Mohan Ghosal, M.B.Calcutta, Robert John Gittins, M.D.Birm., Leo Barclay Heath, M.B.Sydney, Albert Remington Hobbs, M.D.Brux., L.R.C.P., Benjamin Brian Hosford, M.D.Lond., Harold Parnell Jameson, M.D.Birm., Pandipeddi Kutumbiah, M.B.Madras, Sydney Charles Lewson, L.R.C.P., Thomas Mortimer Ling, M.B.Oxf., Gunvantrai Bhagwatidas Mankad, M.D.Bombay, Hugh Leslie Marriott, M.B.Lond., Stanley Melville, M.D.Brux., Ralph Henry Morley, M.B.Lond., Nathoobhai Dayalji Patel, M.D.Lond., William Gilchrist Patterson, M.D.Edin., Walter Maurice Ramsden, M.D.Lond., Sris Chandra Ray, M.B.Calcutta, Brian Fitzgerald Russell, M.D.Lond., John Howard Simmons, M.B.Lond., John Gordon Thomson, M.B.Edin., Gilbert Reynolds Troup, M.B.Melb., George Jasper Wherrett, M.D.Manitoba, John Wolstencroft, L.R.C.P.

Licences.

Licences were granted to the following candidates (including 17 women), who had passed the Final Examination in medicine, surgery, and midwifery of the Conjoint Board in England:

W. Addey, S. Ahmad, H. F. Apthorpe Webb, P. B. Ascroft, F. I. Ashton, J. C. Banerjea, A. Barber, F. R. Beetham, J. E. L. Bendor-Samuel, K. C. Bhattacharyya, J. G. Bowen, B. R. Bramwell, W. J. Burgess, A. C. Byles, W. H. N. Cant, A. Caplan, C. L. Carter, *†Rosa E. Chamings, F. W. Chippindale, D. O. Clark, †B. S. Cornell, D. W. C. Cox, H. J. Croot, J. E. Curnock, R. E. S. Dalliwall, H. L. G. Davies, E. Dikshitulu, *C. de M. Dorey, †A. N. Duggal, C. M. Duncan, F. B. P. Evans, H. R. Ferguson, *Doreen P. Firmin, R. H. Franklin, J. F. Galpine, A. J. Gibbs, E. J. Goldsmith, *Rebecca Goldstein, R. T. S. Goodchild, D. R. Goodfellow, R. K. Goyal, *Charlotte Gray, †A. H. Gurney, B. Halfpenny, R. S. Harrison, J. E. McC. Harrisson, W. Heard, *Aureval Heaton, *Katherine M. Heberlet, L. Hershfield, P. Y. Hicks, R. S. Hodge, H. B. Hough, *Eugenie C. Illingworth, H. B. Jackson, W. D. G. James, J. L. Jekyll, E. K. Jones, G. L. Jones, H. J. Knight, E. O. Lakey, G. F. Langley, L. J. Lannaman, R. O. Lee, A. Lister, E. L. Littler, W. E. B. Lloyd, V. J. Lopez, P. A. T. Lowden, F. D. MacCarthy, *Laura H. Macfarlane, H. A. McGregor, G. K. McKee, F. M. Macleod, J. S MacVine, †E. Marks, I. W. Matheson, F. C. Mayo, B. R. Medlycott, S. J. Mehta, P. D. Mottet, G. na-Ranong, L. B. Neel, A. H. Nelson, †H. P. Nelson, J. E. Newton, A. P. M. Page, H. N. Palmer, R. A. H. Pearce, A. Phillips, W. Phillips, L. D. Pringle, *Ruth Pumphrey, *†Alison J. Rae, D. S. Raju, H. Ramsay, P. V. Reading, J. G. Reid, B. C. Rennie, *Colleen Rice, J. F. Riches, E. H. Rink, S. L. Robert, B. P. Robinson, *(Mrs.) Alice I. Roughton, H. K. Said, J. F. Sandow, N. D. Sane, S. Segalov, R. L. Sethi, D. P. Settna, G. C. Sheldon, *Helana Sidarous, H. Silverstein, *Margaret Skelton, L. A. H. Snowball, R. G. Sowter, H. H. L. Spitz, R. T. Squires, R. Stanley, A. E. Stevens, E. N. Stevens, N. Stevens, F. H. Stevenson, *Ada M. W. Stewart, T. S. Stone, S. Le R. Switzer, P. H. Taylor, D. M. Thomas, V. Thorne Thorne, D. P. Turner, S. C. Wake, *Doris E. C. Walker, E. M. Ward, J. N. Warren, A. J. Whitaker, A. J. White, G. W. Whittall, R. C. Williams, E. R. Willis, H. M. Yardley, B. Yuill.

* Women Candidates.
† M.R.C.S. previously granted.

Diplomas.

The following diplomas were conferred jointly with the Royal College of Surgeons:

PUBLIC HEALTH.—D. D. Anderson, S. Atta Ullah, B. N. V. Bailey, M. K. Biswas, Gwenddolen J. Brooke, I. Caley, H. D. Chalke, Victoria M. Crosse, Jane G. E. F. Cummins, N. C. Dasgupta, A. N. Duggal, J. B. Ellison, R. F. Fidler, S. J. Firth, Annie M. Gamble, T. S. Gill, S. A. U. Haque, L. W. Hearn, G. H. Hogben, J. D. Hourihane, D. F. Johnstone, M. L. Kalra, Y. M. Khan, R. A. V. Lewys-Lloyd, E. A. Lumley, R. M. Macfarlane, M. Mitman, S. K. Mitra, P. McG. Moffatt, C. G. MacM. Nicol, P. Pattabhiramaiya, J. R. Pierre, S. L. Rikhye, Dora F. M. Rose, A. C. Sinclair, E. R. Smithard, R. C. Suri, H. W. Tilling, P. M. Wagle, Ethel M. Weir.

PSYCHOLOGICAL MEDICINE.—D. I. Cameron, J. Carse, H. A. Cooper, R. T. Hay, J. F. MacMahon, J. D. W. Pearce, Margaret A. Quine, A. Shepherd, J. G. T. Thomas, G. S. Wilson, H. L. Wilson.

LARYNGOLOGY AND OTOLOGY.—W. M. Brown, S. Debono, D. N. Ghosh, G. B. Girgis, S. K. Jatar, V. Kathirgamatamby, J. G. Kingsbury, F. E. Littlewood, M. MacGregor, N. M. Macindoe, H. G. Mitchell, J. H. Otty, M. D. Patel, D. R. Paterson, P. Pattabhiramaiya, T. Prasad, D. H. Rao, S. L. Vella.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons this week discussed the Consolidated Fund Bill and went into committee on the Coal Mines Bill. The House differed with the House of Lords about the period for which the Unemployed Insurance Bill is to be valid. The Lords proposed one year, but the Government suggested three. A Slaughter of Animals Bill was down for discussion in the Commons on February 7th. In the House of Lords, on February 4th, the Road Traffic Bill was read a third time.

The second reading of the Mental Treatment Bill was put down for February 3rd in the House of Commons, but was not reached, and there appeared to be no likelihood of the Government moving it later in the week.

The Parliamentary Medical Committee's conference with representatives of the British Medical Association will not be held on February 11th, as at first arranged, but the committee will that day meet representatives of nursing organizations to hear statements about the registration of nurses and the work of the General Nursing Council. Mr. Remer's bill on the registration of mental nurses is postponed pending this month's meeting of the Royal Medico-Psychological Association.

At its meeting, on January 28th, the Parliamentary Medical Committee agreed unanimously on the desirability of Government inquiry into the general conditions of deaf and dumb persons and of those deafened by disease or accident. The committee arranged that Mr. Somerville Hastings should write to the Minister of Health on the subject. The committee discussed the position under the new Poor Law system of doctors who are employed by an authority and are also members of that authority. Representatives of the British Medical Association are to confer with the committee on this issue. The committee also talked about the General Nursing Council and the retention on the list of nurses of the names of nurses convicted of misdemeanours. In the discussion with Sir Hubert Bond which followed, members of the committee asked many questions concerning the Mental Treatment Bill. Discussion turned on two points: the first was whether the supervision of voluntary boarders by the Board of Control might prevent people seeking early treatment; the second was whether the bill would give more powers to the Board of Control at the expense of the Ministry of Health. The Medical Committee took no decisions on these questions. It did not arrange to see the Minister of Health concerning them, nor did it suggest amendments to the bill.

The Conservative Health and Housing Committee also considered the Mental Treatment Bill, Dr. Fremantle presiding.

It was arranged that Sir Kingsley Wood and Sir Boyd Merriman should speak on the second reading. The Conservative party will not divide against this, but will raise legal points in committee.

Psittacosis.

Mr. Greenwood was asked by Mr. P. J. Hannon, on January 30th, whether his attention had been called to a statement by the medical officer of health for Birmingham that several cases of psittacosis, definitely caused by infection from parrots, had occurred in Birmingham within the past two years, and that out of eleven cases four had proved fatal. Mr. Greenwood replied that this medical officer had made no public statement. Investigations into the disease were still in progress. Dr. Vernon Davies asked whether Mr. Greenwood knew that both Germany and the United States of America had prohibited the importation of parrots. No answer was returned.

Children on Canal Boats.

In the House of Commons, on January 31st, Mr. Harry Gosling moved the second reading of the Canal Boats Bill, the purpose of which is to prohibit, under penalty, the residence of children under 15 years of age in canal boats. He said the measure was strongly supported by the National Society for the Prevention of Cruelty to Children, which had found no adequate way to prevent child labour and to provide for education save by removal of the children from the boats. He said that at Paddington sanitary inspectors allowed house refuse to be shot into barges where there were women, and perhaps babies, in the cabins. These women and children were associated with the rubbish during a seventeen-mile journey to the dump, because the women were useful in the manipulation of the boats.

Sir Herbert Nield quoted from the report for 1928 made to the Ministry of Health by Mr. Llewellyn, that department's inspector under the Canal Boats Acts. The inspector reported that infectious disease had been very rare on the boats, and cases of infringement of the regulations seemed fewer each year. The medical officer of health for Birmingham reported that the general health of canal boat people was good; no case of illness was discovered among 3,522 persons who occupied the boats examined by him during the year.

Mr. Beaumont pointed out that Mr. Neville Chamberlain's Committee on Canals said it could not assert that the health of the canal boat children was worse than those living in crowded cities. The same committee found that the children did not appear so liable to infectious diseases as those on shore, but it had recommended that they should not live on the barges during the school terms.

Mr. West quoted Mr. Llewellyn's report for 1926, which said there was no need for any person other than the steersman on boats carrying street refuse and other unpleasant substances.

Miss Susan Lawrence said the Public Cleansing Commission reported that children should not be allowed to live on barges loaded with refuse. When these barges reached their destinations the children got out and played on the dumps.

Sir Donald Maclean announced that the friends of the bill were willing to limit its penal provisions to those who kept children of school age on canal boats. The promoters of the bill were prepared to say that children should be taken from the refuse boats and housed ashore.

Mr. Somerville Hastings contended that, on grounds of health and well-being, a good case could be made out for the exclusion of all children from barges. The inspector of canal boats wrote, in 1926, that, so far as narrow boats were concerned, there was no decrease in the numbers of women and children, and the personal conditions on these boats left much to be desired. Mr. Hastings declared that on a wet and windy night it was practically impossible to keep the barge cabins ventilated without water falling on the beds. Bargees as a class suffered much from respiratory diseases and pneumonia, and the conditions of the life were equally bad for children. Where children were crowded in illness they did badly.

Dr. Fremantle said that, from the point of view of health, he remained unconvinced even after hearing Mr. Hastings. The bill concerned 3,000 children at most. The life of the people on the barges was chiefly outside the cabins, to which they resorted only to sleep—hardly ever for food. People living an open-air life did not find rain a serious inconvenience. He found no evidence in the records of any damage to health. The medical officer of health for Birmingham said nothing on the subject of health. There was less infection for these children in these close, confined cabins, because it could only come from their own families. Would members who supported this bill bring in another bill forcibly to remove children from tuberculous families?

The Duchess of Atholl reminded the House that the Chamberlain report pointed out how unsuited a cabin 9 ft. long and 6½ ft. wide was for a woman's confinement. Yet 1,500 children had been born in these boats in the last nine or ten years. It was not always easy to get medical attention for the woman. There was danger of drowning and of death by fire for young children on a canal boat. Children were employed in steering, in opening locks, and even in hauling boats at some of the locks. The great mass of the boatmen on the canals had their families on shore, and the problem affected fewer than 500 families.

The bill was read a second time by 189 to 64, and by 153 to 44 was committed to a standing committee.

Leprosy in India.

In a reply to Major Graham Pole, on January 31st, Mr. Wedgwood Benn said the number of persons in India returned as lepers at the census of 1921, the last official figure available, was 102,513, but the actual number was probably considerably in excess of that returned. There were about forty institutions with about 8,000 inmates. The Indian Lepers Act provided that the compulsory segregation of pauper lepers might be enforced in areas to which the Act was made applicable by the Provincial Governments, but the number of compulsorily segregated lepers was at present inconsiderable. The number of lepers segregated in their homes and the total amount contributed from Indian revenues for the extinction of the disease could not be stated. Mr. Benn added that the following note had been supplied by Sir Leonard Rogers:

"Any attempt at general compulsory segregation is impossible on account of the prohibitive cost, and now that the improved treatment enables most early, but few advanced, cases to be cleared up, compulsion does more harm than good by causing the early, largely uninfective, cases to be hidden until they have become advanced, infectious, and incurable. At the present time about one hundred doctors are being trained in the modern treatment at the Calcutta School of Tropical Medicine, and thousands of lepers are now being treated by them all over India at clinics, with far greater effect in reducing leprosy than attempts at segregation, which have invariably proved very expensive failures in all tropical countries where they have been tried."

Medicine in India.

Mr. Benn told Major Pole, on February 3rd, that the Government of India was anxious to introduce the necessary legislation to establish an All-India Medical Council at the earliest possible date. It was, however, doubtful whether that would be possible during the present session of the Indian Legislature.

Dr. Fremantle asked Mr. Benn to do his utmost to impress on the Government of India that, unless there was reciprocity between the two Governments and the two Medical Councils, Indian practitioners would be debarred from the possibility of practice throughout the rest of the British Empire, and that it was therefore extremely important to keep the General Medical Council and the Medical Council in India working together. Mr. Benn replied that the Government of India was fully aware of the facts mentioned by Dr. Fremantle.

Mr. Benn, on February 3rd, informed Major G. Pole that the Government of India had decided, after full consideration, to adhere to the proposal to locate the Central Research Institute at Dehra Dun. Their reasons were explained in a debate in the Council of State on September 17th. In his question Major Pole alleged that there was a scarcity of clinical facilities at Dehra Dun.

Diphtheria Death Rate in Certain Countries.

On February 3rd Mr. Greenwood, in reply to Mr. Freeman, circulated the following statement in tabular form, showing the death rate from diphtheria per 10,000 of the population in certain countries for the years 1920 to 1928.

Country.	1920.	1921	1922.	1923.	1924.	1925.	1926.	1927.	1928.
England and Wales ..	1.5	1.3	1.1	0.7	0.6	0.7	0.8	0.7	0.8
Scotland	1.5	1.3	1.1	1.0	0.9	1.0	1.0	1.0	1.0
United States of America*	1.5	1.8	1.5	1.2	1.0	0.8	0.8	0.8	0.7
Germany† (including deaths from croup)	1.3	1.0	0.7	0.7	0.6	0.5	M. 0.4 F. 0.3	M. 0.5 F. 0.4	Not available
Canada‡	Not available	2.0	1.6	1.3	1.3	0.9	0.8	1.1	1.0

M. = Male. F. = Female.

* Rates for years 1920-26 are taken from *Mortality Statistics*, 1926, and relate to registration area of 1920. Rates for years 1927 and 1928 are taken from Public Health Report No. 51, 1929, and relate to registration area of 1922.

† The rates given refer to deaths from diphtheria and from croup, and in respect of the years 1920-25 are taken from *Die Bewegung der Bevölkerung im Jahre 1924*, and relate to the Deutsches Reich; the rates for 1926 and 1927 are taken from *Statistisches Jahrbuch für das Deutsche Reich*, 1929, and are exclusive of the Saargebiet.

‡ The rates given for the years 1921-26 are taken from *Vital Statistics*, 1926, and relate to registration area as of 1921—that is, excluding Provinces of Quebec, Yukon, and North-West Territory; the figures for 1927 and 1928 are taken from *Preliminary Vital Statistics*, 1927 and 1928, and relate to registration area as above, but including Province of Quebec.

Silicosis.

On January 30th Mr. CLYNES told Mr. Cecil Wilson that he had generally approved the medical arrangements recommended by the departmental committee on the diagnosis of silicosis, and a bill to give effect to them was in preparation. He had already acted on the committee's recommendation for further research by arranging with the Medical Research Council for appointment of an expert committee. Mr. Clynes also informed Mr. Morley, on the same day, that the Medical Research Council, at his request, were setting up a committee to institute and co-ordinate research into the subject of scheduling fibrosis of the lungs under the Workmen's Compensation Act. This committee was practically complete and would be appointed shortly. In reply to Mr. Lambert, Mr. Clynes said he had not received any protests from local authorities against the inclusion in the Sandstone Industry (Silicosis) Scheme, 1929, of workmen engaged in the open-air quarrying of stone for road work. He did not propose to modify the statutory rules to exclude such workmen. Cases of silicosis found among quarrymen and others engaged in manipulating sandstone proved that, notwithstanding that the industry was an open-air one, the risk was by no means slight, and there was no evidence of any immunity among those so employed.

Tuberculosis in the Services.—Mr. SHAW told Dr. Vernon Davies, on January 29th, that 165 men were discharged from the Regular Army in 1927 for pulmonary tuberculosis. Of these cases 57 were accepted as attributable, and awarded pensions, while 77 were awarded non-attributable gratuities. To 31 neither gratuities nor pensions were granted. In 1928 the number discharged for the same reason was 184, of whom 58 were accepted as attributable and received pensions, 77 were awarded non-attributable gratuities, and 23 received neither. Mr. MONTAGUE, answering a question on the same day from Dr. Vernon Davies about pulmonary tuberculosis in the Royal Air Force, said that in 1928 pensions were granted to 5 post-war cases and refused to 13 non-attributable cases. In 1929 pensions were granted to one great-war case and 10 post-war cases, but were refused to 15 cases.

Notes in Brief.

Statutory declarations of conscientious objection to vaccination in England and Wales were 277,169 in the year 1928. The figure for 1929 was not available on January 30th.

Mr. Greenwood does not consider it necessary in present circumstances to introduce legislation making it obligatory upon a medical practitioner to view a body after death before giving a death certificate.

Of 52,727 blind persons registered in England and Wales on March 31st last, 37,563 are unemployable.

In the year ended March, 1929, 2,781,877 dog licences were issued in England and Wales, and 171,141 in Scotland. The total for Great Britain in that year was 2,953,018, against 1,978,440 in 1914.

On January 28th Mr. Greenwood said he could not give a definite date for legislation amending the Children Act, 1908, to make it compulsory upon intending foster parents to apply to the local authority concerned for registration of their premises for the reception of infants before reception.

Mr. Buxton is considering a scheme for developing research into animal diseases. He proposes to include swine fever in the expanded programme of work.

Fifty-five local authorities have desired the Ministry of Health to consider the question of allowing municipalities to provide facilities for reliable and private information concerning birth control.

The Services.

ARMY GOLF MEETING, 1930.

THE annual meeting of the Army Golfing Society will be held on the links of the Prestwick Golf Club at Prestwick, Ayrshire, on Tuesday, April 29th, and following days.

The officers of the Royal Army Medical Corps have always taken a great interest in this society, and the present honorary secretary and treasurer is Major T. J. Mitchell, D.S.O., R.A.M.C. (12, Moray Place, Edinburgh). The present Director-General A.M.S. captained the following R.A.M.C. team, which won the Army Golf Challenge Cup at St. Andrews four years ago: Lieut.-General H. B. Fawcus, Major T. J. Mitchell, Major D. C. Monro, and Major P. E. D. Pank. General Fawcus and Major Mitchell have also won the chief handicap cups, and two other officers of the R.A.M.C.—Major F. Chandler and Major E. A. Strachan—won the foursome competition. Intending competitors at this year's Army Golf Meeting should send their entries to Major Mitchell not later than Monday, March 31st.

DEATH IN THE SERVICES.

Lieut.-Colonel Charles Alfred Stone, R.A.M.C. (ret.), died at Frinton-on-Sea on January 20th, aged 63. He was born at Bermuda on June 21st, 1866, was educated at Queen's College, Cork, and graduated as M.B. and Ch.B. in the Royal University, Ireland, in 1889. Entering the army as surgeon on February 1st, 1890, he attained the rank of lieutenant-colonel on May 21st, 1912, and retired, on reaching the age of 55, on June 21st, 1921. He served throughout the South African war of 1899–1902, when he took part in the relief of Mafeking, in operations in Rhodesia in 1899–1900, and in Cape Colony in 1900–2, and received the Queen's and King's medals, with two clasps each.

Medical News.

MEMBERS of the Panel Conference and many other readers will be interested to hear that Dr. Charles W. Graham of Silloth has been invited by the B.B.C. to broadcast vocally from Glasgow on Tuesday, February 11th, from 5 to 5.15 p.m.

A DINNER of the London Jewish Hospital Medical Society, in honour of Professor Neumann of Vienna, will be held on Sunday, February 9th, at 7.15 p.m. for 8, at the First Avenue Hotel, High Holborn. Application for tickets (price 6s. 6d.) should be made to Mr. M. Sourasky, 59, Queen Anne Street, W.1.

THE annual general meeting of the Medical Officers of Schools Association will be held at 11, Chandos Street, Cavendish Square, W.1, on Friday, February 21st, at 5 p.m.; tea at 4.30. Dr. G. E. Friend will deliver the presidential address, entitled "Some notes on the value of clinical, dietetic, and physical records in public schools" (illustrated by lantern slides and diagrams).

A PROVINCIAL meeting of the Maternity and Child Welfare Group of the Society of Medical Officers of Health will be held at Bristol on February 20th and the two following days. Papers will be read on nasal hygiene in infants, the difficult child, respiratory disorders of infancy, congenital and postural deformities in children, and eye conditions in the pre-school child. Visits will be paid to various medical institutions in the neighbourhood, and excursions will be arranged. Further information may be obtained from Miss Grace Calver, 1, Holly Terrace, Highgate, N.6.

AT the meeting of the Royal Sanitary Institute on February 15th, in the Town Hall, Ipswich, discussions will take place on new methods of sewage disposal in Ipswich, and on meat inspection. The chair will be taken at 10.30 a.m. by Dr. Charles Porter.

THE eighteenth annual series of Chadwick Public Lectures will begin on Thursday, February 13th, when Dr. B. Blacklock, recently Director of the Alfred Lewis Jones Research Laboratory in Sierra Leone, and now professor of parasitology in the Liverpool School of Tropical Medicine, will lecture on "Health in West Africa." Dr. Blacklock will show pictures of the country and of methods of combating the diseases formerly so devastating. Sir James Crichton-Browne will preside. Admission is free. Particulars of future Chadwick Lectures may be obtained from the Secretary, Mrs. Aubrey Richardson, at the offices of the Trust, 204, Abbey House, Westminster.

A NEW post-graduate course at the National Hospital, Queen Square, W.C.1, began on February 3rd. It consists of out-patient clinics, clinical lectures and demonstrations, lectures on the pathology, anatomy, and physiology of the nervous system, and clinical demonstrations on methods of examination. The fee for the course, including pathology demonstrations, is £6 6s.; for those holding perpetual tickets or clinical clerks, £4 4s. Full particulars can be obtained from the Dean of the Medical School.

THE Fellowship of Medicine announces that Dr. M. B. Ray will lecture on the role of hydrology in medical practice on Tuesday, February 11th, at 4 p.m., in the lecture room of the Medical Society, 11, Chandos Street, Cavendish Square. There will be a clinical demonstration by Mr. Cecil Rowntree at the Cancer Hospital, Fulham Road, at 2.15 p.m., on February 13th. At the Paddington Green Children's Hospital, on February 14th, at 4 p.m., Dr. D. W. Winnicott will give a lecture-demonstration on anxiety in children. This lecture and the demonstrations are free to medical practitioners. A course in gynaecology at the Chelsea Hospital for Women, from Monday, February 10th to 21st, will consist of lectures and demonstrations in the operating theatre. A course of eight clinical demonstrations will be given at the Hospital for Tropical Medicine, from February 11th to March 6th, on Tuesday and Thursday afternoons, at 2 o'clock. A four weeks' course in dermatology at St. John's Hospital, Leicester Square, from February 17th to March 15th, will comprise clinical work every afternoon and lectures twice weekly; instruction in pathology can also be arranged. From February 24th to March 8th a course in the diseases of children will be held at the Children's Clinic and other hospitals, occupying the afternoons and some mornings. An afternoon course in the diagnosis and treatment of diseases of the eye will be given at the Royal Eye Hospital from February 24th to March 8th. In March there will be courses in diseases of the chest at the Brompton Hospital, neurology at the West-End (Nerve) Hospital, and venereal diseases at the Lock Hospital. A special two weeks' course of lectures and demonstrations will be held at the Royal National Orthopaedic Hospital, Great Portland Street, from March 10th to 22nd. Those taking the course will have access to operations and the practice of the hospital. Application

should be made to the secretary of the hospital or to the secretary of the Fellowship of Medicine, 1, Wimpole Street, London, W.1, from whom may be obtained syllabuses of the various courses.

THE Child-Study Society, London, has arranged the following lectures and discussions to be held on Thursdays at 6 p.m. at the Royal Sanitary Institute, 90, Buckingham Palace Road, S.W.: February 20th, "Homeless children," Miss Muriel A. Payne; March 13th, "The new prospect for our adolescents," Mr. R. A. Raven; April 10th, "Parent education: the home and the school," Dr. Ralph H. Crowley; senior medical officer, Board of Education; May 8th, "The re-education of the difficult child," Mr. T. J. Faithfull.

A SERIES of lecture-discussions on mental health and the child will be delivered under the auspices of the National Council for Mental Hygiene in the lecture room of the Medical Society of London, 11, Chandos Street, Cavendish Square, W.1, on Wednesdays, at 5 p.m., from February 26th to April 2nd. Dr. Hugh Crichton-Miller will open the course with a lecture on the new psychology and the parent, and on March 5th Dr. Letitia Fairfield will speak on the subject of the child and the teacher. Mr. W. Clarke Hall will give an address on the delinquent child, on March 22nd, and on the following Wednesday Dr. William Moodie will discuss the problem of the difficult child at home and at school. Mrs. Neville-Rolfe will speak on sex education on March 26th, and Dr. R. D. Gillespie will close the course, on April 2nd, with an address on choosing a career. Tickets, price 1s. 6d. for each lecture, or 7s. 6d. for the course, may be obtained from the secretary of the National Council for Mental Hygiene, 78, Chandos House, Palmer Street, S.W.1, or at the lecture room.

THE William Julius Mickle Fellowship, awarded annually to the graduate of the University of London "who has done most to advance medical art or science in the preceding five years," has been awarded to Dr. H. A. Harris, assistant professor of anatomy, University College, and assistant to the medical unit, University College Hospital.

THE committee of management of Queen Charlotte's Hospital has, on the recommendation of the medical staff, decided to appoint a paediatrician to the hospital, and Dr. Eric Pritchard has, at their invitation, accepted this office. It is understood that this appointment, which is allowed by the courtesy of the committee of management of the Infants Hospital, will not in any way conflict with Dr. Pritchard's work as medical director of that institution. Dr. J. Hartley Gibbens has been appointed assistant to Dr. Pritchard.

THE January issue of the *Journal of the Association of American Medical Colleges* appears in two parts. The first includes the address delivered by the president, Dr. Burton D. Myers, at the fortieth annual meeting of the association, held in New York last November, together with statistical accounts of the achievements of candidates for admission to various medical schools in the United States during recent years. There is also an article on State Boards and medical schools by the secretary for the Board of medical examiners in the University of New York, and one on the teaching of therapeutics. The second part—issued as a supplement—gives a list of fellowships and prizes available for medical graduate work offered by the medical schools of the United States and Canada. This periodical—which now appears six times a year—is published from 25, East Washington Street, Chicago, at 3 dollars a year; single copies, 75 cents.

WITH a view to reporting more widely the medical and surgical investigations in progress in South America a new journal, entitled *Revue Sud-Américaine de Médecine et de Chirurgie*, has now appeared, and will be published monthly in French in Paris. The first issue, dated January, 1930, contains original articles by medical practitioners in the Argentine, Bolivia, Brazil, and Chile, together with reviews of publications in South American countries, and summaries of the contents of various journals and bulletins. The *Revue* is published by Masson et Cie, 120, Boulevard St. Germain, Paris, and the stated price for an annual subscription of twelve copies is, in France and her colonies, 100 fr., and for other countries 120 fr., or 12 fr. for a single issue.

THE centenary of the birth of the Freiburg gynaecologist, Alfred Hegar, who was born on January 6th, 1830, and died on April 5th, 1914, has been commemorated by Professor Ernst Sonntag, his son, Professor Karl Hegar, and Professor Paul Diepgen of Freiburg in the issue of the *Deutsche medizinische Wochenschrift* for January 10th.

AN outstanding feature of the Malayan Medical Service list for October, 1929, is the high proportion of appointments above the time scale, of which there are no fewer than 57 as against 88 on the scale. The Service includes 17 women, who seem to enjoy the status of full establishment, as their names are not (like those of their fellows in West Africa) relegated to a separate list, which does not indicate any fixed scale of pay.

PROFESSOR K. F. WENKEBACH, who recently resigned his chair of clinical medicine at Vienna, has succeeded the late Professor Clemens Pirquet as president of the Austro-American Institute of Education in Vienna.

THE Department of Health for the Commonwealth of Australia has issued an epidemiological record of the Austral-Pacific Zone for the year 1928. This annual publication makes available a systematic record of the principal facts and occurrences of interest to medical men concerning numerous Pacific islands about which information is often difficult to obtain. It is published by authority of the Minister for Health by H. J. Green, Government Printer, Canberra.

A PARTY of doctors, conducted by Dr. Friedrich Barach, will leave Vienna on April 18th, on a visit to Spain, for the purpose of studying medical organization. The journey will be broken at Venice, San Remo, Mentone, Monte Carlo, and Nice. The party will visit Dr. Voronoff at Château Grimaldi, and then proceed to Barcelona and Madrid. Medical practitioners who wish to accompany the party are invited to apply for further information to Aerztliche Auslandsstudienreisen, Biberstrasse 11, Wien, I.

ALTHOUGH small-pox was less prevalent and not so virulent in the United States during the first six months of 1929 as in the corresponding periods of 1928 and 1927 three States had mortality rates of more than 1 per cent. No State reported cases in excess of 2,000, and no case was reported in the District of Columbia. The Province of Saskatchewan in Canada reported three deaths in the first half of 1929 among 65 cases, giving the relatively high case fatality of 4.62 per cent.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62559 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

LANOLINE AND THE GROWTH OF HAIR.

"SENEX" writes: I should be glad to have the opinions of some of your readers on the following: A good-looking, athletic young lady, aged 20, suffers from general dryness of the skin, especially on the face and neck. To improve her appearance she has been in the habit of frequently using lanoline. Both she and her mother are now worried about a growth of hair on her face, which they attribute to the lanoline. I should like to know: (1) does lanoline stimulate the growth of hair; (2) would a course of thyroid extract improve the dryness of the skin?

INTESTINAL FLATULENCE.

"FLATULENTISSIMO" would like to know if saxin, 1½ to 2 grains taken daily for about twenty years, would be at all likely to aggravate extreme intestinal flatulence. The patient suffers from pancreatic insufficiency, with negligible glycosuria, but extreme intestinal flatulence and atony of the colon. Intestinal antiseptics and endocrine preparations are absurdly futile in their effect.

BUCCAL ULCER.

"R. D." writes: A healthy woman, about 40, has had for the past three years, with only short intervals of complete freedom, successive crops of ulcers appearing on the inside of the cheeks and lips, also on the tongue, soft palate, and uvula. Having tried most of the known remedies, I should be grateful for suggestions as to treatment.

THE ETERNAL COLD QUESTION.

"CURED" writes: "H. H." should improve the vasomotor tone of the mucosae (he may then let organisms take a second place in his treatment). Thus:—*Fauces, tonsils, pharynx:* Make a habit of swabbing out daily before retiring with 3 per cent. silver nitrate solution, later increasing to 5 per cent. Use a thin wooden aural applicator dressed with smallest quantity of cotton-wool, and dab on quickly before a hand mirror; the retching reflex with practice becomes insignificant. *Nasal mucosae:* Make a habit of spraying by "glaseptil" pocket nebulizer with chlore-tone inhalant; it is best to do this also at night and after contact with infectious persons. Occasionally swab the mucosae with 5 per cent. argyrol; later on change for 3 per cent. silver nitrate solution. *Laryngeal mucosae:* A pinol and menthol inhalant vehicle—rectified spirit) may be used, a few drops being placed on the handkerchief daily; also keep down the irritation with menthol and eucalyptus lozenges. Having suffered previously for years, the above routine now keeps me free.

EFFECT OF TROPICS ON MENORRHAGIA.

"O. M.," replying to the inquiry in the *Journal* of January 25th (p. 179), writes: With the experience of twenty years' general practice in the tropics, and being well acquainted with the climatic conditions mentioned, I would advise decidedly against the patient being allowed to go out—first, on account of the menorrhagia, and secondly, on account of her not being robust. None but quite physically fit women should go out; ignoring climatic conditions only leads to invalidism, and she would almost certainly have to be sent back to a temperate climate before the end of a few months.

ABDOMINAL SURGERY AT SEA.

CAPTAIN A. F. W. DA COSTA, I.M.S. (Camp Sibora, India), writes: With reference to the inquiry by "T. S. S." in the *Journal* of September 28th, 1929 (p. 604), about a book on operative surgery (abdominal) for emergencies, I think he could not do better than invest in a copy of *Lejar's Urgent Surgery*. I consider that Treves and Hutchinson's *Handbook of Surgical Operations* is much on the short side.

INCOME TAX.

Resident Patient.

"W. E. M." has a resident patient who pays £5 5s. per week. Would he be justified in deducting £100 per annum for her board and lodging?

*** On the facts stated we think the amount is justifiable, provided that our correspondent is not claiming to deduct, say, one-half of the cost of rent, rates, etc., and a part of the cost of domestic service from general practice profits. If he is in such practice and has made such a claim, he should bear in mind that it is only that part of the general expenses not deducted from general profits which can properly be allocated to the expense of lodging the resident patient.

Subscriptions to Professional Societies.

"A. J. W." asks whether the annual subscription to a particular medical society can be treated as a professional expense.

*** Yes; but if the income from which the deduction is sought to be made is a salary, then the amount cannot legally be deducted unless the employer has made it a condition of the appointment that membership of the society in question shall be maintained.

"A. H. C." inquires similarly with regard to other subscriptions.

*** (1) London and Counties Medical Protection Society: if the local inspector of taxes is not convinced by production of the society's printed statement that the subscription can be deducted, "A. H. C." might ask the society to communicate direct with the inspector. (2) British Medical Association: the subscription is usually allowed under Schedule D. (3) Society of Medical Officers of Health: we have no evidence that this subscription is allowable. It may be that the difficulty in "A. H. C.'s" case is not the identity of the professional societies, but the condition referred to in the reply to "A. J. W." printed above.

LETTERS, NOTES, ETC.

FOXGLOVE AT THE BEDSIDE—AND ELSEWHERE.

DR. F. J. ALLEN (Cambridge) writes: Some fifty years ago a friend of mine in Somerset met a rustic carrying a large bundle of foxgloves, when a conversation occurred somewhat as follows: "What are you going to do with those foxgloves?" "Take them home to my wife; she makes foxglove tea of them." "*Foxglove tea!* Why, don't you know they are rank poison?" "No; *that* I don't. My wife has got the dropsy, and foxglove tea does her a world of good." Thus this drug, which doctors administer with so much caution, was being taken in a perfectly casual way by an ignorant person. I have met with no other similar case; but it seems possible that the use of foxglove for the treatment of dropsy was traditional, and had existed from time immemorial.

MENTAL DISORDER AND INTESTINAL SEPSIS.

DR. JAMES CRAIG (Glasgow) writes: I am sure we are all indebted to Dr. Joyner of Torquay for his description of the illustrative case in the *Journal* of January 11th (p. 89). I have seen many such in my lifetime. When lecturing on jalap my old materia medica teacher used to hold up a piece of the root and say, "Gentlemen, Shakespeare says in one of his plays, 'Canst thou not minister to a mind diseased?' Well, then, this is my verdict, that jalap is the most effective remedy in mind disease." How often in these long years of practice have I found the truth of this statement! Every mother knows the magical effect of castor oil on refractory or bad-tempered children who suffer from constipation. A good deal of my work is among the aged, and I find many of them irritable, opinionative, and difficult to deal with on account of constipation or imperfect evacuations of the bowel. Grey powder, rhubarb, and soda administered four-hourly have a most beneficial effect on such cases. I am afraid free purgation is being neglected in these days of over-refinement in drug treatment, and special appeals to the palate in food and other things.

LARGE HYDROCELES.

DR. P. M. SHEPHERD (Uburu, Southern Nigeria) writes: Medical men in practice in tropical countries are familiar with cases of large hydroceles; I wonder how the following compares with the experience of others as regards size? An old man came here recently with double hydrocele. The fluid in the left sac measured 61 oz. and in the right 40 oz. The usual radical operation was performed, and the patient made a good recovery.

ST. DUNSTAN'S.

BEARING the title "Fifteen Years After," the fourteenth annual report of St. Dunstan's, for the year ended March 31st, 1929, takes the form of a historical survey of the activities of St. Dunstan's during the period which has elapsed since its foundation. The council pays the highest tribute to those people all over the Empire who, from the beginning, have given the organization their sustained and generous support, and it is interesting to read that the Empire-wide work of St. Dunstan's has been rendered possible entirely by voluntary financial effort. Last year the council initiated an exhaustive inquiry to discover as nearly as possible how much further financial help the organization would require, and for how long it would be needed. It was estimated that if St. Dunstan's continued to receive its present measure of financial support it would be able, within the next fifteen years, to set aside from its necessary annual expenditure a sum which would provide a capital endowment sufficient to make further appeals unnecessary, and yet to ensure the continuance of the present standard of benefit to every war-blinded man coming under the influence of the organization. It is gratifying to note that already there is a surplus of income over expenditure, and that the first step towards the endowment has therefore been taken. At the present time the St. Dunstan's community comprises 1,907 ex-officers and men and 4,977 wives and children. The report is illustrated throughout by photographs depicting every phase of life at St. Dunstan's.

THE BRITISH INDUSTRIES FAIR.

THE British Industries Fair, organized by the Department of Overseas Trade, is being held at Olympia, London, from February 17th to 28th. An advance copy of the catalogue which has reached us contains descriptive entries relating to the exhibits of some 1,800 British manufacturers. Drugs and pharmaceutical preparations have an entire and representative section to themselves, and so have medical and surgical instruments and appliances, though this latter section seems unexpectedly small, with only five exhibitors of surgical instruments and only three of *x*-ray and electro-medical apparatus. Scientific and optical instruments, however, will be shown in great profusion, and illustrate every class of optical requirement. Fifteen firms show manufactures of hospital ware. A valuable feature of the catalogue is the alphabetical list of the exhibits, which is really a dictionary of trade and technical equivalents in nine languages. The catalogue as a whole ought to be a corrective to pessimism concerning British manufacturing enterprise.

THE GULF STREAM MYTH.

DR. J. M. MCNAMARA (London, W.) writes: I have pleasure in replying to Dr. Elliot's friendly letter. The article I referred to is "The lore of the wanderer," in the *Castleknock Chronicle*, June, 1927. Should Dr. Elliot want more information on the subject he will find it in *Physiography*, by Huxley and Gregory (Macmillan and Co., 1919 edition, p. 199, etc.). Under the article "Atlantic Ocean," in the ninth edition of the *Encyclopaedia Britannica*, the subject is ably treated by Dr. W. B. Carpenter. I may add that my being set right on the subject of the Gulf Stream I owe to the courtesy of the editor of *Nature*.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 42, 43, 44, 45, 48, 49, and 50 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 46 and 47.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 43.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

132. Established Hypertension without Cardiac Hypertrophy.

CH. AUBERTIN (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, December 9th, 1929, p. 1371) finds that a certain small proportion of patients in whom hypertension exists as the sole cardio-vascular defect show no signs of cardiac enlargement either clinically or by *x*-ray examination. An account of three such patients is given; they were all between 50 and 60 years of age, and had blood pressures in the neighbourhood of 230 systolic and 120 diastolic. In two of them hemiplegia had previously occurred, and indicated a long-standing high blood pressure, but in none of them was any enlargement of the heart found by orthodiagram. Similar findings have also been made at necropsies by Dumas when the death had supervened from such accidental and unrelated causes as epilepsy or malignant disease, in patients suffering from permanent hypertension. The present author admits that cases of this kind are relatively rare, and quotes a number of cases in which cardiac enlargement of varying degree was found after death resulting from cerebral lesions, bronchitis, or cardiac failure. Where hypertension had been associated with chronic renal disease and insufficiency, gross cardiac enlargement was the rule, these hearts being twice as heavy as those found in the author's quoted series of necropsies on cases of uncomplicated hypertension. The scarcity of observations on cases of this kind is commented upon, and Vaquez and Bordet are cited as noting the occasional absence of left ventricular hypertrophy in aged subjects of hypertension, and as remarking upon the predominance of atheroma in the pathological picture. From his observations Aubertin concludes that while hypertension associated with renal or cardiac disease gives rise to cardiac enlargement fairly early, pure hypertension reacts in this way very late, if at all.

133. Circulatory Failure in Diphtheria

F. F. SCHWENTKER and W. W. NOEL (*Bull. Johns Hopkins Hosp.*, November, 1929, p. 276) divide all cases of circulatory failure in diphtheria into two groups: in one the collapse occurs at the height of the disease, and in the other at a later stage. The circulatory disturbance of the early type is due either directly or indirectly to the action of diphtheria toxin upon the circulatory system. According to Warthin the essential pathological lesion in the diphtherial heart is a marked parenchymatous degeneration of the heart muscle, varying in degree with the severity of the process and with the stage of the disease. In almost every case there is hyaline degeneration or necrosis; the hyaline change may be the only parenchymatous lesion present, or it may be associated with fatty degenerative infiltration, or with cloudy swelling, or with both. Occasionally there is simple necrosis of individual fibres. In late cases, in addition to the above changes there is a regenerative process which consists of a lymphocytic and polymorphonuclear infiltration about the small vessels in the stroma of the damaged portions of the muscle. The regeneration of the heart muscle is accompanied by a parallel proliferation of the stroma.

134. Reaction of Old Vaccination Scars in Revaccination.

O. J. POOL (*Nederl. Tijdschr. v. Geneesk.*, December 7th, 1929, p. 5720) vaccinated a girl, aged 13, with three insertions in the right thigh. Fourteen years previously she had been vaccinated for the first time on the left arm over the deltoid in five places, where the scars were still distinct. Not only was the revaccination successful, but each of the five scars of the primary vaccination became red and swollen, and subsequently became covered with fine brown scabs. Although this phenomenon has not been previously described, Pool states that several of his colleagues have had a similar experience.

135. Trophic Ulceration following Lethargic Encephalitis.

E. SCHITTLER (*Schweiz. med. Woch.*, November 9th, 1929, p. 1121), who records an illustrative case, remarks that while the psychical sequels of lethargic encephalitis are well known, records of vasomotor and trophic sequels are much rarer. It is generally supposed that they are associated with changes in groups of ganglion cells which are situated in the region of the third ventricle and possess vegetative and trophic functions. These trophic changes consist in dystrophia adiposo-genitalis, vasomotor skin changes, such as a greasy face, Quincke's oedema, vesiculo-squamous eruptions, gangrene, increase of diminished sweat secretion, sialorrhoea, and facial atrophy. Schittler's patient was a boy, aged 14, who developed extensive ulceration of the right nostril and adjacent region of the cheek as a sequel of an attack of lethargic encephalitis in association with typical symptoms of Parkinsonism. The ulceration gradually healed, but the patient died the following year from pneumonia.

136. Remote Prognosis in Pneumonia.

H. P. JAMESON (*Arch. Dis. Child.*, December, 1929, p. 365) examined the after-histories in a series of fifty-eight children treated during the last ten years for pneumonia lasting more than three weeks at the Hospital for Sick Children, Great Ormond Street, London, and the Children's Hospital, Birmingham. He found that one-third were without symptoms and one-third suffered severely with pulmonary catarrh. During the examinations evidence accumulated that two factors were almost of equal importance in the production of symptoms: first, the amount, duration, and recurrence of the interstitial inflammation; and secondly, periodic infections from the upper respiratory tract. It seemed over and over again that both were necessary for the production of severe symptoms of chronic or recurrent pulmonary catarrh. Second and third attacks are of importance as another cause of mischief.

137. Prodromal Rashes of Small-pox.

ACCORDING to M. TSUREMI (*Bull. Off. Internat. d'Hyg. Publ.*, November, 1929, p. 1891), during the period of June, 1917, to May, 1918, of 103 cases of small-pox admitted to the hospital for infectious diseases at Darien, 39 showed a prodromal eruption. It is probable that the actual incidence was higher, and that in several patients the rash had faded on admission to hospital; it assumed one of three forms: scarlatiniform, morbilliform, or haemorrhagic. The eruption was most marked on the outer side of the upper arm—that is, in the site chosen for vaccination—unless more than ten years had elapsed since the last vaccination, when the tendency was no longer observable. Although it is generally supposed that prodromal eruptions are almost confined to mild cases, 9 of the present series were severe and 4 fatal. A prodromal eruption, therefore, cannot always be regarded as a favourable sign.

Surgery.

138. Acute Prostatic Abscess.

W. G. S. HOPKIRK (*Kenya and East African Med. Journ.*, November, 1929, p. 230) reports a case of prostatic abscess which illustrates the damage that may result from unskilled syringing and the taking of alcohol. He considers that these are the two most important factors in the causation of posterior urethritis and therefore of chronic gonorrhœa. The patient had been treating a urethral discharge by syringing himself with a permanganate solution. Acute posterior urethritis followed, and acute retention ensued, necessitating suprapubic puncture of the bladder. Perineal prostatotomy was performed, and an abscess cavity was found and drained: complete recovery followed. Hopkirk remarks that, although acute prostatitis and prostatic abscess are most commonly gonorrhœal in origin, they are not infrequent in cases of senile enlargement of the prostate, and may occasionally appear also in the course of a general infection, such as influenza, pyæmia, or furunculosis. The abscess originates in a number of necrotic spots scattered through the substance of the gland. These enlarge, coalesce, and form an abscess cavity. Both lobes of the prostate are usually affected; the abscess lies posteriorly and in the closest contact with the urethra, into which it usually bursts, when spontaneous cure may result, though the imperfect drainage afforded by the small opening renders it more probable that chronic prostatitis will ensue. In view of this and also of the danger of a recto urethral fistula resulting, Hopkirk advises drainage of a prostatic abscess by the perineal route. He thinks this should always be undertaken if marked improvement does not quickly follow spontaneous rupture into the urethra; if spontaneous opening is delayed and the general symptoms are severe; or if there is evidence of inflammation round the prostate. The principal difficulty of the operation is the liability to tearing of the rectal wall; this occurred in Hopkirk's case.

139. Congenital Dislocation of the Hip.

F. MANDRUZZATO (*La Chirurgia degli Organi di Movimento*, October, 1929, p. 200) has studied the statistics of cases of congenital dislocation of the hip dealt with between 1899 and 1927 in the orthopaedic clinic of the University of Bologna. His report is based on 2,578 patients, of which 2,192 (85.02 per cent.) were females and 386 (14.58 per cent.) males. Bilateral dislocations amounted to 42.94 per cent. and unilateral to 57.06 per cent.; of the latter variety, 39.02 per cent. affected the right hip and 21.83 per cent. the left. The percentages in the two sexes were as follows. (1) Females: bilateral 36.96, unilateral—right-sided 29.82, left-sided 17.72; (2) males: bilateral 5.97, right-sided 5.39, and left-sided 4.11 respectively. The influence of heredity was clearly indicated in 502 cases out of 2,276, a direct causation being evident in 6.54 per cent. and an indirect familial in 16.69 per cent. These percentages of congenital causation are lower than those of Vogel (30 per cent.) and Le Damany (42 per cent.). Birth injury as a factor seems to have little influence in causing dislocation; of 2,297 cases 83.45 per cent. were born normally. The percentages in respect of age in 2,482 children were: in 88.43 per cent. the disability appeared with the first attempts to walk; in 5.03 per cent. within the first five years of life; and in 1.08 per cent. after the age of 5. Out of the total number of patients 88.48 per cent. received treatment by circumduction, and 3.16 per cent. by operation.

140. Treatment of Renal Lithiasis.

A. L. CHUTE (*Minnesota Med.*, December, 1929, p. 731) advocates the early removal of renal calculi, though he is prepared to watch those of less than 5 to 6 mm. in diameter. Early removal is especially important if the kidney is infected or single; with bilateral calculosis the better kidney should be operated on first. When both the kidney and the ureter of the same side contain stones they should be operated on at the same time, or the renal stone may be removed first and the ureter dealt with as soon as possible thereafter. Relatively small uninfected calculi in the renal pelvis should be removed by pyelolithotomy, the pelvis being generally opened on its posterior surface and in the direction of its long axis. Nephrolithotomy is the operation the author generally performs, and he incises the kidney on its convex surface just behind the mid-line. Care should be taken that every fragment of a stone or all multiple stones are removed, the kidney being irrigated with sterile water if necessary. The author passes a soft drainage tube of one-quarter inch diameter with a "fishtail" end down to the renal pelvis, bringing together the kidney tissue by deep catgut sutures on either side of this tube. His rule for ureteral calculi is removal if there is any particular degree of infection, or if more than moderate pain or occasional disability is caused. Immediately before the operation he verifies his diagnosis by the passage of an *x*-ray catheter. In cases of non-infected small stones low in a ureter, "dilatation" with one or more ureteral catheters may be tried. The usual oblique kidney incision is used for ureteral calculi down to the lower border of the third lumbar vertebra. In stones still lower the incision should start a fingerbreadth internal to the anterior superior spine, and extend downwards parallel with the fold of the groin, and about three-quarters of an inch internal to it, ending above the pubis; or a straight incision should be made along the outer edge of the rectus muscle. The ureter should not of choice be opened in the depths of the pelvis, the stone being either "milked" up, or grasped and withdrawn with a curved stone forceps introduced through an incision an inch or two above the impacted stone, or pushed through into the bladder with a probe. Closure is expedited if the edges of the incision in the ureter are brought together with 0 or 00 catgut. A rubber wick should be carried down to the incision.

141. Secondary Megoesophagus.

G. PECO (*Rev. Med. Lat.-Amer.*, November, 1929, p. 208), who records four illustrative cases in patients aged from 31 to 62, maintains that in every case of megoesophagus it is important to exclude any local organic lesion of the oesophagus. When an oesophageal cause has been excluded, a gastric factor must be suspected, especially gastric cancer, ulcer, or gastritis. Duodenal ulcer and cholelithiasis are the next most important possibilities. Causes not connected with the alimentary tract include any visceral or nervous lesions which can act reflexly on the nerve supply of the oesophagus. It is important to determine whether stenosis of the oesophagus is produced by spasm or achalasia. Obstruction at the lower end of the oesophagus may be due to hypotonus of the vagus or hypertonus of the sympathetic. In two of Peco's cases the megoesophagus was due to a gastric tumour; in one it was secondary to well-marked neurosis in an arterio-sclerotic subject; and in the fourth to an ulcer of the lesser curvature of the stomach.

Therapeutics.

142. Contraindications to a Saltless Diet in Nephritis.

P. DELAFONTAINE (*Paris Méd.*, December 7th, 1929, p. 506) states that though a diet from which salt is excluded is of remarkable efficacy in nephritis, there are cases in which such a regimen is contraindicated. An azotaemic syndrome of hypochloridation due to a lack of sodium chloride may occur in certain nephritic patients. Blum, van Caulaërt, and Grabar divide cases of nephritis into two groups—those with and those without oedema. In the former the adoption of a saltless diet is definitely indicated, but in the latter it is necessary to distinguish azotaemic and non-azotaemic forms. In the latter of these there is no chloride deficiency, and a saltless diet is not contraindicated, though the reduction of salt must be governed by the degree of chlorine retention. In the non-oedematous types with azotaemia, salt should not be prohibited. The diagnosing of hypochloridation is not always easy, and laboratory examinations of the serum or plasma chlorine are indispensable, and also of the alkaline reserve; if this reserve is normal there is a chloride deficiency. Should the acidosis be very marked, with only a moderate chloride diminution, the chloride is to be considered excessive; if these conditions are reversed there is a chloride shortage. In certain cases additional tests are necessary, such as the establishing of the ratio between the whole blood chlorine and the plasma chlorine. Blum believes that the lowering below normal of the chloride titre of the cerebro-spinal fluid is a certain indication of hypochloridation. Delafontaine states that salt should be given in nephritis whenever a chloride deficiency can be proved, but that its administration should be controlled by careful observation and repeated laboratory investigations.

143. Treatment of Cerebro-spinal Syphilis.

E. C. MENZIES (*Canadian Med. Assoc. Journ.*, November, 1929, p. 534) describes the active treatment of cerebro-spinal syphilis as carried out at the Verdun Protestant Hospital, Quebec. Before the introduction of tryparsamide in 1923 practically all cases of this disease terminated fatally. Of 41 patients treated with tryparsamide and mercury from 1923 to 1925, 9 are still progressing satisfactorily; and of 40 patients treated by means of malaria followed by tryparsamide and bismuth, 16 show improvement. Malaria followed by tryparsamide is a much more adequate treatment than the latter alone, as it is much quicker, and in some cases forestalls hopeless degeneration; the danger of optic atrophy is much less; and a much higher percentage of patients obtained satisfactory remissions. Though the use of tryparsamide alone is to be deplored, it has distinct value when used subsequently to fever therapy, and may possibly be beneficial when the patient's physical condition is clearly such that malarial inoculation would be fatal. Induced malaria is easy to stop, and is not infective. In the present series the improvement among women was, if anything, better than among men. The results have been so marked that Menzies maintains that no patient suffering from any form of neurosyphilis should be certified before malaria is tried. Non-specific therapy succeeds not so much because of a direct spirochaeticidal action, but because it enlists and stimulates the natural resistive forces of the patient—the same means whereby any infection is overcome. The value of careful nursing, good food, fresh air, and sunlight must be remembered in connexion with treatment.

144. Vaccine Treatment of Whooping-Cough.

N. J. SPYROPOULOS (*Paidoterapia*, October, 1929, p. 5487) has treated large series of cases of whooping-cough by injections of ether, protein therapy in the form of sterilized milk, and specific vaccines respectively, and comes to the following conclusions. Injections of ether are valueless; there was no evidence in favour of their efficacy either in complicated or uncomplicated cases. Heterologous protein therapy also has no value in the treatment of complicated or uncomplicated whooping-cough; moreover, subcutaneous injections of sterilized milk almost always produce a febrile reaction. Specific vaccine therapy can be applied on a large scale with a certain degree of confidence. Its success is undoubted during the catarrhal stage, its administration is harmless and painless, and the results are all the more likely to be successful the earlier it is applied. The same vaccine has hardly any effect when used at the height of the disease, and especially in old-standing cases.

145. K. KYRIAZIDÈS (*Paris Méd.*, November 30th, 1929, p. 473) records his observations on 113 cases of whooping-cough treated in the Evangelismos Hospital at Athens during the epidemic of 1924–25; in 88 the diagnosis was confirmed by bacteriological examination. His conclusions were as

follows. Vaccine therapy undoubtedly exercises a very favourable influence on the disease, the best results being obtained by a mixed vaccine prepared from the various organisms swarming in the pharynx and upper respiratory tract. The number of injections ranged from two to five, and the dose from 25 to 500 million bacilli, according to the severity of the case. The injections were given in the gluteal region. The result of the treatment was to shorten the course of the disease, prevent complications, and to cure them when they developed. In cases where an autogenous vaccine was not available good results were also obtained from a mixed stock vaccine; the earlier it was employed the better were the results; when given in the catarrhal period it had an abortive effect.

Neurology and Psychology.

146. Intestinal Origin of some Personality Changes.

G. W. DRAPER and R. K. JOHNSON (*Amer. Journ. of Surg.*, October, 1929, p. 568) describe the personality of a child as a growing and expanding thing which is subject to variations very early in life. Unfavourable personality changes in childhood, unless checked, may take on a directional trend or may be the first symptom of important physical derangement. Children who show abnormal alterations in personality are always physically ill in some form or other; sometimes the removal of focal infections of the throat and nose may cure them, and sometimes the trouble is caused by gastro-intestinal disorders. In 50 per cent. of cases mental dysmorphism, with angular, rotatory, and constricting deformity of the bowel, is found; various degrees of megacolon, megasigmoid, and megacaecum are encountered, while acute appendicitis is not uncommon. There may also be persistent urinary changes with early nephritis, under-nutrition, secondary anaemia, diabetes insipidus, asthma, and neurological disturbances, chiefly psychotic and epileptiform. Treatment of such cases must involve the prevention of colonic degeneration based upon surgical therapeusis. It is contended that the groundwork for many forms of chronic disability is laid down during intrauterine life and can be found in early childhood, and that the gastro-enterologist is best fitted to discover and correct fundamental abdominal defects. Out of 41 children and adolescents with enteric dysmorphism, 35 exhibited personality changes; 23 were operated on, with good results in many cases, the degrees of improvement varying from complete to partial restoration of personality.

147. Tumours of the Fourth Ventricle.

CERTAIN authors, notably van Bogaert and Martin, have attempted to attach a specific syndrome (the cerebellar syndrome of the median line) to tumours of the fourth ventricle, which would facilitate their recognition and permit of an early surgical intervention. J. A. BARRÉ, J. STOLZ, and ALFANDARY (*Rev. de Méd.*, November, 1929, p. 869) do not consider that this is possible; they maintain that the diagnosis of these tumours remains extremely difficult, if not impossible in certain cases, and they agree with Cushing that a symptomatology exists for each tumour. In support of this view a case is reported of a lad, aged 18, who developed in the course of a year a syndrome of cranial hypertension and vestibular troubles, very prominent on the right side, and with a special alteration of the caloric sense which could be considered as expressing a left labyrinthine are reflectivity. Only a few days before operation some very discrete cerebellar troubles, limited almost exclusively to the right side, developed. There were no violent headaches with pains radiating to the neck, shoulders, and arms, no rigidity of the cervical muscles, and no hyperflexion or hyperextension of the head. Early troubles of micturition, which many authorities ascribed to disturbances of the pyramidal tracts, were absent, as was also ataxia of both the upper and lower extremities. The patient died, and the post-mortem examination revealed a large tumour, which filled the whole of the fourth ventricle, infiltrating its roof and floor; from it there passed a large prolongation through the greatly deformed foramen of Magendie, and two others through the foramina of Luschka. The latter covered the sides of the ponto-bulbar region, separated the base of the almonds, and involved the trunks of the seventh and eighth pairs of nerves. In reality three tumours existed: a central ventricular was associated with two lateral ones which merited the name of ponto-cerebellar. The right one of the lateral growths was hard, and was situated between the mammillary tubercle and the optic chiasma; the left, which was larger and soft, was found between the almond and the bulbo-protuberantial axis. Histologically the tumour proved to be a young, very cellular ependymoma.

148. The Early Diagnosis and Treatment of Anterior Poliomyelitis.

R. G. GORDON (*Bristol Med. Chir. Journ.*, Winter, 1929, p. 283) draws attention to the three stages, described by Walshe, in the development of the illness. The first stage is that of general invasion, with coryza, tonsillitis, or diarrhoea and vomiting, the discharges being infective material. In the second, the meningeal stage, there is headache, with pain in the limbs and back, fretfulness, sometimes apathy and coma, and rarely delirium and convulsions. The meningeal stage may follow the general stage rapidly, or there may be an interval of one or two days. The third stage is that in which the virus attacks some part of the neuraxis. Wickman's classification, modified by Collier, of the types of the disease is as follows: (1) the sub-clinical type, carriers; (2) the abortive case, stages 1 and 2 only, with complete recovery in a few days; and (3) the spinal case with involvement of the anterior horn cells, pain and tenderness in the affected muscles, and, possibly, a transverse myelitis with spastic paralysis below the lesion and paralysis of the bladder reflexes; (4) the neuritic type; (5) the spreading type; (6) the meningeal type; (7) the cerebellar type; (8) the so-called brain-stem type, probably encephalitis lethargica; (9) the cerebral type; (10) relapsing cases; and (11) mixed types. For treatment massive doses of one to two drachms of hexamine daily, with alkalis, may be useful. Lumbar puncture is of value in establishing the diagnosis and in relieving symptoms, such as pain and restlessness. The author is of opinion that every case which is not abortive should be nursed on a frame for at least two months, when the patient may be taken off for a few minutes daily for careful massage of weak muscles. Electricity should be given late. Fatigue or over-stretching of the affected muscles will destroy all chances of recovery.

149. Disseminated Sclerosis.

L. H. ZIEGLER (*Minnesota Med.*, December, 1929, p. 778) presents a study of 529 cases of disseminated sclerosis, and comments on the variability of the symptomatology. Charcot's triad—scanning speech, intention tremor, and nystagmus—is classic, but many and varying combinations of symptoms occur. Neither heredity nor sex seems to be a causal factor. The disease is usually insidious in onset, and makes its appearance chiefly in the second and third decades of life. The most frequent symptoms of onset are motor or sensory disturbances of the lower extremities, and visual disturbances, including diplopia and central scotoma. The patients associated the disease mostly with pregnancy and parturition, but in a number of cases there was a history of injury. Remission is common as regards single symptoms and signs, but rarely in the case of all the symptoms and signs; striking and long remissions occur. Patients with multiple sclerosis often have emotional disorders; they are euphoric and happy in contrast with what would be expected from the severity of the disability. The clinical causes of death, so far as they could be determined, were pyelonephritis, septicaemia, pneumonia, and intercurrent infection. The disease is progressive and very disabling; the etiology, so far, has not been established, and treatment has to be based on a system of "trial and error." Typhoid vaccine, sodium cacodylate, salvarsan, silver compounds, hydrotherapy, heliotherapy, rest, and good general care have all been recommended, while Eurich has reported that infection with the parasite of benign tertian malaria has given encouraging results in a series of cases.

Obstetrics and Gynaecology.

150. Scanty Menstruation.

I. C. RUBIN (*Amer. Journ. Obstet. and Gynecol.*, November, 1929, p. 603) reports a study of 157 cases of diminished menstruation; the patients applied for treatment on account of abnormality of menstruation, or because of sterility, relative or absolute. In about half the cases the menstrual interval was from six to fifteen weeks; in about one-quarter from sixteen weeks to nine months; and in the rest longer than normal, though less than six weeks. Of the 147 married women in this series 70 per cent. were sterile, and a further 12 per cent. had conceived but not carried to term, or had borne one child only. These figures are compared with a 15 per cent. incidence of sterility among the married female population in general. About one-third of the patients showed aberration of the secondary sexual characters—masculine distribution of the pubic and abdominal hair, with or without general hirsutism. One-third had become markedly heavier, and one-third showed symptoms, mostly mild, of endocrine disturbance. It appeared from examination of 1,000 gynaecological out-patients that about 8 per cent. had some type of diminution in the menstrual flow—38 cases of scanty flow,

24 of delayed periods with normal flow, 15 of delayed and scanty menses, and 9 of delayed and profuse menses. In both series of patients the incidence of sterility was proportional to the prolongation of the menstrual interval, so that patients having an interval of less than one month appear to have five to eight times better chance of conceiving than those whose periods are delayed from four to six months. The delayed character of the periods, their paucity, and the associated sterility are regarded as expressive of ovarian hypofunction, towards the restoration of which treatment must therefore be directed. General stimulant treatment, with improvement of hygienic and psychic conditions, is essential. The administration of ovarian and pituitary extracts, which on theoretical grounds might be expected to be of great benefit, has so far proved disappointing. Mild *x*-radiation of the ovaries has yielded better results, and was followed by speedy pregnancy in 16 out of 33 cases, but Rubin recommends that it be preceded by mild irradiation of the hypophysis. Such a procedure, followed if necessary by *x*-ray applications to the ovaries, was found to cause an approximation of menstrual periodicity to normal in four-fifths of cases, and to increase fertility by 50 per cent.

151. Conduct of the Third Stage of Labour.

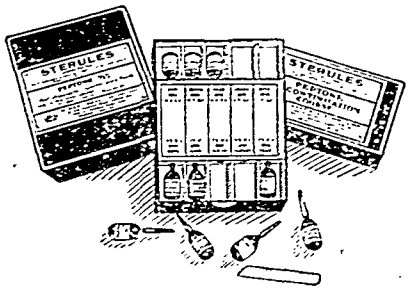
M. LEFF (*Amer. Journ. Obstet. and Gynecol.*, December, 1929, p. 868) discusses the value of vaginal examination in the third stage of labour as a guide to its management, basing his conclusions on a study of 1,000 cases. He criticizes the view that the placenta requires ten to forty-five minutes to separate, and that it is therefore necessary to wait before attempting to express it. By making a vaginal examination soon after the child has been born he has found that the placenta separates promptly after the infant leaves the uterus. He insists that the only positive way of knowing when the time has come to express the placenta is by vaginal examination. The retroplacental hematoma is not a factor in the separation of the placenta, but is the result of its retention in the uterus after separation. The author has found that the cervix frequently closes down on the placenta, and he maintains that no attempt at expression should then be made until it reopens. Although the Credé manœuvre is quite applicable when the placenta presents according to the Schultze method, it is not effective in a great number of cases when the placenta is laterally situated. In the author's 1,000 cases the average time for the delivery of the placenta was four and three-tenths minutes. He adds that, with prompt expression of the placenta, the uterus contracts sooner and more firmly, bleeding being greatly diminished.

152. Treatment of Syphilis during Pregnancy.

J. TORLAIS (*Gaz. Hebd. des Sci. Méd. de Bordeaux*, December 8th, 1929, p. 770) describes the case of a woman, aged 32, who had a series of miscarriages; she eventually gave birth to an infant with stigmata of congenital syphilis which died shortly afterwards. The mother's and father's blood showed a negative Wassermann reaction, but the case was regarded as one of latent syphilis, and when she was again two months pregnant treatment with novarsenobillon was begun. Doses of 0.15 gram and 0.30 gram were well tolerated, but after a third injection of 0.45 gram a morbilliform eruption with fever appeared on the tenth day after beginning treatment, and abortion ensued. Torlais quotes various opinions as to the administration of antisyphilitic treatment to pregnant women. Statistics show that a greater proportion of healthy infants are born after treatment of the mothers with organic arsenical preparations than after mercurialization; opinion is divided as to the dosage, but in general it is recommended that a start should be made with doses from 0.10 to 0.15 gram, gradually increasing for five or six injections, and repeating the course after an interval of two months. Some authors do not give treatment during the last two months of pregnancy, while others advise a very slow rate of increase from a minimal dose, and continue throughout pregnancy; on the whole, opinion seems to be against the supposition that arsenical preparations have any special abortifacient action. Torlais quotes the recent thesis of Garnier, in which it is laid down that cutaneous erythema due to arsenobenzol may be of two main varieties: (1) occurring about the ninth day, corresponding to the eruptions of infectious fevers, and essentially due to exacerbation of the syphilitic infection; and (2) more rare, appearing later and more gradually, of graver import, and showing a true arsenical intoxication. Normal subjects who have had no previous arsenobenzol treatment give a negative reaction to intradermal injection; 90 per cent. of those who will have a "biotrophic" reaction—that is, those coming under the first group—will give a negative reaction, whereas 100 per cent. of those who will show toxic reactions will give a positive reaction. A "biotrophic" reaction is no contraindication for continuation of treatment, whereas a "toxic" reaction should at once forbid it.

Pathology.

153. Crystalline Menformon.



E. LAQUEUR, E. DINGEMANSE, and S. KOBER (*Nature*, January 18th, 1930, p. 90) state that four years ago they gave the name "menformon" to a female sexual hormone—the name indicating a certain degree of purity of the product; about a year and a half ago they obtained a degree of purity amounting to 10 million units per gram. Last August Doisy recorded the preparation of crystals containing 8 million units per gram, and more recently Butenandt described crystals again of the same degree of purity. The present authors remark that, since this substance of Doisy and Butenandt's is no purer than the product they originally described, the giving of the new name "progynon" to the crystalline hormone seems unnecessary. They add that recently J. R. Katz, studying menformon by *x*-ray spectrography, found the structure to be crystalline, and they have now succeeded in obtaining macro-crystals similar to those of Doisy and Butenandt, and containing 78.6 per cent. carbon and 8.25 hydrogen. They agree that it is uncertain at present whether crystalline menformon really constitutes the pure hormone, even when the purity reaches 8 to 10 million units per gram, since, in spite of careful recrystallization, adsorption of the active substance on the crystals cannot be excluded. Moreover, they have already succeeded in three cases in producing a substance of an activity of 14 million units per gram.

154. The Complement Fixation Test in Gonorrhœa.

T. E. OSMOND and J. O. OLIVER (*Brit. Journ. Vener. Dis.*, October, 1929, p. 281) review the results of tests upon more than 5,000 serums from unselected patients, some of whom suffered from gonorrhœa or syphilis, or both, while others gave no evidence or history of venereal infection. After describing their own technique and referring to other methods they conclude, from a classification of the results, that the complement fixation test is remarkably specific, since the percentage of false positive results was as low as 0.6; in all but very early cases a high percentage of positive results was obtained, ranging from 50 to almost 100 per cent. in the cases of gonorrhœa with complications. Usually a positive result is not to be expected during the first ten days of the disease unless complications have arisen; an early positive result probably indicates an extension of the infection to the posterior urethra in the male and to the cervix uteri in the female. A positive result in any stage of the disease is practically diagnostic, while a negative result has a similar significance to a negative Wassermann reaction, since it may occur in any stage, and, except in the differential diagnosis of such complications as arthritis and epididymitis, its value is limited. With regard to the disappearance of the positive reaction with cure, the authors differ from other observers in not regarding the persistence of a positive reaction as absolute proof of a failure to cure; in their experience the change from positive to negative following clinical cure occupies in many cases a relatively long period, while a negative reaction is of value if the case has previously given a positive reaction. They are of opinion that stock vaccines, in the doses usually administered, have but little effect on the result of the reaction, which is more liable to be influenced by an autogenous vaccine.

155. Hepatic Sequels of Disease of the Central Grey Nuclei.

C. OBERLING and A. KALLO (*C. R. Soc. de Biologie*, December 20th, 1929, p. 916) refer to the work of Ricker on the influence of the nervous system on hepatic pathology, and state that a direct relation between the nervous system and the liver is clearly indicated in certain well-known clinical syndromes, such as Wilson's disease. The majority of authors consider that lesions of the lenticular nuclei are consecutive to hepatic lesions, but the converse may be true, and in order to elucidate this point the present authors have made a series of experiments on animals in which the central grey nuclei were destroyed by thermocauterization. On examination the livers showed an intense congestion with small subcapsular haemorrhages, and the parenchyma revealed an exaggerated lobular design resembling the nutmeg appearance of human cardiac liver. On microscopical examination marked evidence of circulatory disturbance was found, with considerable dilatation of the centrolobular capillaries. The hepatic lesions were undoubtedly of a circulatory and angioneurotic order, and appeared to demonstrate that lesions of the central grey nuclei do cause circulatory disorders in the liver. This finding is considered by the authors to be important because it is evident that prolonged disorders of this kind bring about complete alteration of the hepatic structures, and to this can be attributed the nodular hyperplasia which is characteristic of the hepato-lenticular syndrome.

HEALTHY WINDOWS FOR THE SICK ROOM

Unchecked Passage of Ultra-Violet Rays through "Vita" Glass

Natural ultra-violet radiation can penetrate to rooms through "Vita" Glass windows. Ordinary glass acts as a shutter to the ultra-violet rays; it bars them out.

"Vita" Glass, the only British window glass of its kind, gives a permanent passage to the ultra-violet rays. After a short period of exposure to daylight, its power of transmission is stabilized, and a "Vita" Glass window operates as a health measure every daylight hour, summer or winter, whether the window faces north, south, east or west.

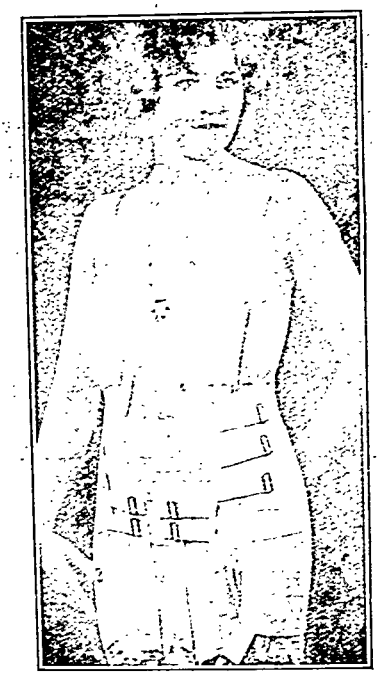
Already nearly 200 hospitals and over 100 schools are equipped with it, as well as numerous factories, offices and private houses. "Vita" Glass is not an expensive measure to prescribe for patients of modest means. For example, a window of average size can be fitted with "Vita" Glass for 38/-, plus the cost of fixing.

Further information about "Vita" Glass will be sent to any Medical man who is interested. Write to: "VITA" GLASS MARKETING BOARD, 9, Crown Glass Works, St. Helens, Lancs. London Offices: Aldwych House, W.C.2.

"Vita" Glass is obtainable from local Glass Merchants, Plumbers, Glaziers or Builders.

"Vita" is the registered Trade Mark of Pilkington Brothers, Limited, St. Helens.

V.201.



For the Relief of Sacro-iliac Relaxation or Strain

in Women or Men

WHEN a sacro-iliac lesion has been caused by heavy lifting, childbirth, bad posture or other conditions, a Spencer Belt relieves the condition by immobilizing the articulations involved.

Fixation of the sacro-iliac joints is achieved by means of this specially designed belt or corset whose inner band, fitted with a pad, acts as a fulcrum in securing proper adjustment.

The sacro-iliac band which is built inside the corset or belt can be adjusted as tightly as necessary from the outside after the belt or corset is in place. Since the band is built into the Spencer Support, it never rides out of position. It holds the body structure in position, thus relieving tension or pressure and hastening the return to normal condition.

SPENCER
SACRO-ILIAC BELT

As the patient's condition improves, a light Spencer Support, without the special sacro-iliac band, often can be substituted for the regular sacro-iliac support.

We issue booklets on the use of Spencer Supports for the relief of hernia, enteroptosis, movable kidney, sacro-iliac strain, and for maternity wear. We will gladly send you any of them.

Each Spencer Support is especially designed for the patient who is to wear it. The Spencer Corsetière in your town will call at your surgery or at your patient's home to take measurements under your supervision.

Spencer Supports and Corsets are never sold in stores.

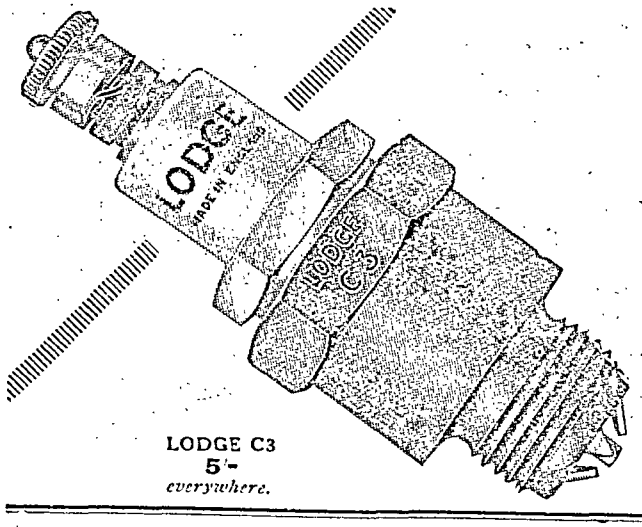
SALT'S COLOSTOMY BELT
WITH STERILIZABLE RUBBER CUP
(REGISTERED No. 749046).

This Belt is specially designed for cases where fæces are of a solid nature or the amount is small.

The special feature is the Cup, which is made of moulded rubber in one piece.

It has no corners or crevices and therefore does not retain the odour.

The advantages in this Belt are:—



1. Detachable Cup sterilizable by boiling, repeatedly without deterioration.
2. No crevices or metal fittings to hold fæces.
3. Smell reduced to a minimum.
4. Minimum of bulk.
5. Cups easily and economically replaced.

HARMFUL THROAT TABLETS. Throat Tablets and Lozenges containing Formalin (Formaldehyde) are harmful. Wiley, of the United States, investigated the effects of small doses of Formalin (Formaldehyde) given with milk, on 12 men during 15 days. Burning in the throat, itching rash, and loss of body weight were observed.—*Vide* Martindale. All countries which have made legal enactments and laws regarding the purity of its food supply have prohibited the addition of Formaldehyde (Formalin) as a preservative of food. HUDSON'S EUMENTHOL JUJUBES contain no Formalin, Cocaine, or other harmful or poisonous drug. Sold everywhere.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one or the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Cliffden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.
Telephone: *Teignmouth* 289.

BELVOIR NURSING HOME,
ASTON-ON-TRENT, DERBY.
FUNCTIONAL NERVOUS DISORDERS & CHRONIC MEDICAL CASES.

The Home, a Georgian mansion, 14 miles from Nottingham and 6 miles from Derby, is for both sexes. In addition to the methods of general medicine, Psycho-Therapeutic treatment is used extensively in suitable cases. Certifiable cases are not received. Electrical treatment, Radiant Heat, X-ray, and Ultra-violet Light is available in the Nursing Home. Billiards, tennis, etc. Fees from 5 to 12 guineas per week; for Chronic Medical Cases from 3 guineas a week. For further particulars apply to—

Dr. E. M. DOUGLAS-MORRIS, ASTON, DERBY. *Telephone*: Shardlow 16.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton-in-Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

Tel.: 64117. *For terms, etc., apply to the Medical Superintendent.*

The MAUDSLEY HOSPITAL
DENMARK HILL, S.E.5.

Telephone: RODNEY 4841—2.

A CLINIC instituted by the London County Council for Treatment of NERVOUS and CURABLE MENTAL DISORDER. Voluntary patients ONLY RECEIVED.

OUT-PATIENTS—2 p.m.: MEN—Mondays and Thursdays. WOMEN—Tuesdays and Fridays.

IN-PATIENTS: (*a*) 164 beds (both sexes) in wards or separate rooms. (*b*) 13 private rooms (for ladies) with special sitting rooms, garden, and dietary.

Terms:

(*a*) **£5** a week, but in case of patients with a legal settlement in the County of London a less sum may be charged according to means.

(*b*) **£6 6s.** a week.

Terms include (with rare exceptions) all forms of treatment, for which exceptional facilities exist—there being a staff of consultant specialists and the central laboratory of London County Mental Hospitals being attached to the hospital. Inquiries of EDWARD MAPOTHER, M.D., M.R.C.P., F.R.C.S., Medical Superintendent.

WONFORD HOUSE HOSPITAL,
EXETER, DEVON.

ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited from duly qualified Medical Men, with a Public Health qualification, for the position of Assistant Medical Officer of Health.

Candidates will be required to carry out medical inspection of school children and child welfare work and perform such other duties as may be allotted as Assistant to the Medical Officer of Health and School Medical Officer.

The person appointed will be required to devote his whole time to the duties, and will not be allowed to engage in private practice. Salary will be at the rate of £600 per annum, rising to £650 by £25 per annum.

A deduction of 5 per cent. will be made from the salary in accordance with the provisions of the Local Government and Other Officers Superannuation Act, 1922, which has been adopted by the Council, and the appointment will be subject to passing the Council's medical examination in connection therewith.

Copies of application form and terms of appointment can be obtained from the undersigned, to whom applications, accompanied by copies of not more than three recent testimonials, must be delivered not later than February 13th.

Town Hall. THOMAS ORR,
Ealing, W.5. Medical Officer of Health.

County Council of Durham.

DEPUTY COUNTY MEDICAL OFFICER OF HEALTH.

The County Health Committee invite applications for the appointment of a Deputy County Medical Officer of Health at a commencing salary of £1,000, rising by annual increments of £50 to £1,200 per annum. Reasonable travelling and out-of-pocket expenses will be paid by the County Council.

Applicants must be duly registered Medical Practitioners holding a degree or diploma in Public Health, and the gentleman appointed will be required to devote the whole of his time to the duties of the office and to reside in the City of Durham or other approved centre.

He will be required to undertake any duties required of him by the Council bearing on the health and medical services of the county.

He will be required to act under the administrative control of, and to be responsible to, the County Medical Officer of Health for his duties.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and to a medical examination as required by the Council for the purposes of the Act, and the statutory contributions to the Superannuation Fund under that Act will be deducted from the salary.

Applications, marked "Deputy County Medical Officer," together with copies of not more than three recent testimonials, must be sent to the County Medical Officer, Shire Hall, Durham, not later than February 19th.

HAROLD JEVONS,
Clerk of the County Council.
Shire Hall, Durham, Feb. 3rd, 1930.

Derbyshire Education Committee

ASSISTANT SCHOOL MEDICAL OFFICER (Male).

The Derbyshire Education Committee require the services of an Assistant School Medical Officer (male) at a salary of £600, rising by annual increments of £25 to £700 per annum.

The candidate must be a registered Medical Practitioner of at least three years' standing. The duties will include work under the Maternity and Child Welfare Service. Experience in this work and in the administration of anæsthetics is essential.

The officer appointed will not be allowed to engage in private or consulting practice, but will be required to devote his whole time to the duties of the office, and will act under the direction of the School Medical Officer.

Forms of application may be obtained from the undersigned, to whom they should be returned completed, together with copies of not more than three recent testimonials, on or before Monday, February 24th, endorsed "Assistant School Medical Officer."

The appointment will be determinable by three months' notice on either side.

New County Offices, W. M. ASH,
St. Mary's Gate, School Medical
Derby. Officer.

The salary commences at £550 per annum, rising by four annual increments of £25 each to £650, with emoluments of the value of £120. An award of £50 per annum will be made to the officer appointed if and when he obtains the Diploma in Psychological Medicine.

Full details of the post, and forms on which *alone applications will be considered,* can be obtained on receipt of a stamped addressed foolscap envelope from the undersigned.

C. W. ALLAN HODGSON, County Offices, Carlisle, Feb. 3rd, 1930. Clerk to the Visitors.

Shropshire Orthopædic Hospital AND AGNES HUNT SURGICAL HOME, OSWESTRY.

HOUSE SURGEON (male) required on April 1st, but it is possible that arrangements could be made for the successful candidate to commence duty at an earlier date.

Appointment for six months, with possibility of extension. Salary at the rate of £200 per annum, with board, residence, and laundry. Two weeks' holiday after each six months' service.

Applications, stating age, with copies of three recent testimonials, should be received by the Secretary-Superintendent on or before Feb. 24th.

Victoria Hospital, Burnley. (120 Beds.)

Applications are invited for the post of HOUSE PHYSICIAN (male). The appointment is for six months, and carries a salary of £125 per annum, with board, etc. This Hospital is approved by the London University for the purpose of the M.B. and M.S. Examinations.

Applications, with testimonials, should be addressed to the undersigned forthwith.

GEO. W. COOLING, Feb. 3rd, 1930. Secretary-Superintendent.

Coventry and Warwickshire HOSPITAL, COVENTRY.

Applications are invited for an HONORARY ASSISTANT DENTAL SURGEON, who must possess a Diploma in Dental Surgery recognized by the General Medical Council of Great Britain, and must be duly registered.

Candidates shall be resident in the City of Coventry, or within six miles thereof, or shall take up their residence within that radius within six months from the date of appointment.

Canvassing, either directly or indirectly, will be deemed a disqualification.

Applications, with original testimonials and registration certificates, must reach the undersigned on or before February 18th.

Candidates will in due course receive notice of their eligibility or otherwise from the Secretary, and after receipt of such notice eligible candidates are at liberty to send through the post printed copies of their application and testimonials to the Members of the Board of Management of the Hospital, a list of whose names and addresses will be furnished by the Secretary.

No such applications or copies of testimonials shall be sent until receipt of such notification from the Secretary.

The appointment shall be made for twelve months, and the candidate appointed shall be eligible for re-election at the end of that period.

The appointment may be terminated at any time by the Board of Management.

By Order of the Board,
(Miss) R. HOOPER,
February 4th, 1930. Secretary.

St. Bartholomew's Hospital, E.C.1.

APPOINTMENT OF DENTAL HOUSE SURGEON.

Applications are invited for the office of House Surgeon to the Dental Department.

Candidates must hold a registrable Dental qualification. A Medical qualification in addition is desirable but not essential. Appointment will be made for six or twelve months. The salary attaching to the office is £80 per annum, non-resident.

Applications must be left with the undersigned on or before Friday, February 21st.

THOMAS HAYES,
Feb. 1st, 1930. Clerk to the Governors.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880.)

12, Stratford Place,
Oxford Street, W.1.

Tele. Address: Triform, Wesdo—London.

Telephone: Mayfair {1782 / 1783}

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

10-13, BEDFORD STREET, STRAND, LONDON, W.C.2.

Telegrams: BOVMEDICAL, WESTRAND-LONDON. *Telephone*: TEMPLE BAR 1616 (3 Lines).

Under the personal direction of Dr. J. FIELD HALL and Mr. J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants.
Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. PARTNERSHIP.—SURREY.—Residential district within 20 miles of London. A one-quarter share is offered in an exceptionally sound mainly better and middle-class Practice, having scope for increase. Income over £6,000. Fees 5/- to 21/-. Particularly nice house, with 7 bedrooms, etc. Large garden. Price for freehold about £2,200. Premium 2 years' purchase.
2. EASTERN COUNTIES.—PARTNERSHIP.—Third share of old-established mixed-class and increasing Practice in small pleasant market town in an agricultural district. Cash receipts last year over £3,100, including appts. worth £300 and panel with mileage producing £500. Visits 3/6 to 15/-. Opposition slight. Railway station. Compact house (consulting and waiting rooms, 2 sitting, 5 bedrooms, dressing and bathroom, etc.). Garden. Garage. Price, freehold, £900. Premium 2 years' purchase.
3. DEATH VACANCY.—LONDON, S.W.—Old-established non-panel PRACTICE, producing over £1,600 p.a. Fees from 2/6 to 21/-. Convenient house, with 2 reception, 4 bedrooms, and professional rooms, etc. Rent on lease £110 p.a. Premium £1,500. Locum in charge.
4. SUSSEX.—Unopposed old-established Village PRACTICE in delightful surroundings, producing about £1,100 p.a., including panel of 545, *and capable of considerable increase. Exceptionally charming* residence standing in 1½ acres of well-laid-out garden, tennis court, etc., and containing lounge hall, 2 reception, 7 bedrooms (3 fitted h. & c. water basins, dressing and 2 bathrooms, etc. Central heating. Electric light. Garage. Price, freehold, £3950. Premium £1,650.
5. HOME COUNTY.—Near Sea.—Old-established unopposed Country PRACTICE in pretty district. Receipts last financial year £1,123, including union, etc., £55, and panel 400. Railway station near. Good house in own grounds (about one acre, but more can be had if wished), containing 2 reception, 6 bedrooms, etc. Water laid on and electric light available. Price, freehold, £1,650. Premium £1,625. Educational facilities and sport.
6. PARTNERSHIP.—OXON.—Delightful residential district near good town.—A one-third share (to commence with) in an old-established *good mixed-class Practice, averaging for the past three years £1,540,* and offering good scope. Panel of nearly 1,000. Fees 3/6 to 21/-. Choice of two houses at rentals of £100 and £50 p.a. Sport of all kinds. Premium 2 years' purchase.
7. SUSSEX COAST TOWN.—PARTNERSHIP.—A one-fifth share, to commence with, is offered in an old-established mixed-class Practice producing last year over £4,000 p.a., including panel of 2,200. Fees 3/- to 10/6. *Good house, with 2 reception, 6 bedrooms,* and professional rooms. Electric light. Garden. Garage. Rent on lease £100 p.a. Premium 2 years' purchase. Short preliminary assist'ship.
8. MIDLANDS.—COUNTY TOWN.—PARTNERSHIP.—A one-fourth share in an exceptionally sound non-dispensing mainly mixed and better-class Practice, averaging over £8,500 p.a. Small selected panel of 700. Fees 5/- to 21/-, average 7/-. Suitable house can be obtained. *London, Oxford, or Cambridge Graduate preferred,* age 30 to 35, and experienced in anæsthetics. Premium £4,000.
9. NEAR LEICESTER.—Old-established good middle-class Country PRACTICE, in attractive district. Average income £1,453, including panel of 1,250. Fees from 3/6. Mid. 3 gns. upwards. Good house in excellent repair, 3 reception, 6 bedrooms, etc., separate professional rooms. Garage. Garden of 3½ acres. Price freehold £2,800. £1,750 on mortgage, or might be rented. Premium £2,175.
10. SOUTH DEVON.—PARTNERSHIP.—Attractive Town close to sea.—A half share in a very old-established and rapidly increasing mixed general Practice. Average cash receipts for last 3 years £2,727, last year £3,521. Panel of 1,130. Fees 3/6 to 21/-. Good house in *its own grounds with ample accommodation.* Price freehold £1,900, £1,200 on mortgage. Premium £2,500. Cottage Hospital, and good scope for major surgery.
11. BORDERS OF NORTHANTS AND LINCS.—Unopposed old-established Country PRACTICE, within easy reach of large town, and worth over £1,500 p.a., including panel (with mileage) £675, and appts. about £80. Visits 5/- to 20/-. Suitable house available. Rent £70 p.a., or can be bought. Premium 1½ years' purchase. Held by Vendor, who is retiring, over 30 years. Sport of all kinds.
12. NEAR LIVERPOOL.—Mainly better working-class PRACTICE, producing about £700 p.a., including panel of 854. Fees 2/6 to 5/-. Mid. 3 to 5 gns.; about 20 cases yearly. Suitable house available on rental. Premium £1,000.
13. WITHIN 100 MILES OF LONDON.—PARTNERSHIP.—A share producing about £1,200 p.a., with prospects, is for disposal owing to the retirement of one of the partners in an old-established Practice. Ingoing partner would reside in a pretty country district about 5 miles from pleasant country town, where main practice lies. No opposition. Total income about £8,000, including valuable appointments worth about £2,000, and panel. Very desirable residence (ample accommodation) with 2½ acres of ground available on lease at low rental of £60. Premium 2 years' purchase.
14. LIVERPOOL.—Middle and working-class PRACTICE. Receipts for immediate past twelve months £1,247, including panel of 602. Fees from 2/6. Suitable house, with 2 reception, 4 bedrooms, etc. Large garden. Price for leasehold £1,550, of which £1,300 could remain on mortgage. Premium £1,550.
15. LONDON, S.W.—Old-established middle-class PRACTICE, producing over £1,000 p.a., including small panel of 380. Fees 2/6 to 7/6. Mid. lately refused. Good corner house, with ample accommodation. Rent on lease £115 p.a. Premium 1½ years' purchase.
16. SOUTH COAST.—FAVOURITE HEALTH RESORT.—*Old-established mixed-class* PRACTICE, producing about £1,000 p.a. *Small panel of* 283. Fees from 2/6. Suitable house, with 3 reception, 5 bedrooms, etc. Large garden. Price for leasehold £1,400, £1,250 on mortgage. Premium £1,200.
17. YORKS.—(North Riding).—*Country PRACTICE in beautiful district. Average income* over £750, including panel of about 350. Fees 3/6 to 21/-, medicine extra. Nearest opponent 4 miles. Suitable house with 2 reception, 4 bedrooms, etc., and garden of 1 acre. Rent on lease £30 p.a. Prem. 1½ years' purchase, part by instalments.
18. LONDON, W.—Chiefly *middle-class PRACTICE*, averaging about £700 p.a., including panel of 750. Visits 3/6, 5/-. No midwifery. Suitable house, with 4 beds., etc. Rent on lease £96 p.a. Prem. £1,100.
19. MANCHESTER DISTRICT. — Old-established middle and working-class PRACTICE, worth last year about £700, including panel of 590, *and capable of increase.* Expenses small. Well-situated house, with 6 rooms in addition to professional rooms. Large garden. Price, freehold, £850. Moderate *premium accepted.*
20. CHANNEL ISLANDS.—Old-established better and middle-class PRACTICE, averaging about £1,000 p.a., but capable of increase. Fees 5/- to 21/-. *Little midwifery.* No panel. Large well-situated house with garden. Garage for 3 cars. Very pleasant social conditions. Premium for Practice *and house £4,000, of which £1,500 to £2,000* could remain on mortgage.
21. KENT.—Old-established Country PRACTICE, in favourite locality, and within 5 miles of the coast. Income for past 12 months £1,185, and increasing. Visits 5/- to 21/-. Panel of about 380. Appts. worth *about £50 p.a. Convenient house,* with ample accommodation. Nice garden. Price for freehold £1,800. Premium 1½ years' pur.
22. WITHIN TWENTY MILES OF LONDON.—Old-established good mixed-class PRACTICE, in attractive residential district. Receipts average £1,000 p.a. Panel of nearly 500 and appts. worth £60. Visits 3/6 to 21/-. Very nice house, with all modern conveniences and half acre of garden. Price for freehold £1,800. Premium £1,400.
23. DEATH VACANCY.—NORTH WALES.—Easily worked *PRACTICE*, offering large scope, in beautiful seaside and country district. Cash receipts for last twelve months about £1,200. Very convenient and commodious house can be rented on lease at £85 p.a. Premium £800. Very good Locum in charge.
24. HOME COUNTIES.—*Within few miles of large town.—Old-established* unopposed and increasing PRACTICE, in pleasant district, worth over £3,000 p.a., including panel, with mileage, producing about £1,000 and appts. £260. Visits 3/6 to 10/6, medicine usually extra. Very little midwifery. Good house (7 bedrooms, etc.), garden, garage. Price, freehold, £2,000. Premium 1½ years' purchase.
25. CHESHIRE.—Industrial Town within easy reach of Manchester.—*Well-established PRACTICE producing £2,600 p.a., with panel of* 2,870. Fees 2/6 to 3/6, medicine extra. Good house, with ample accommodation. Price £1,000; or would be rented at £70 p.a. Premium 1½ years' purchase, half down and balance by instalments.
26. SOUTH AFRICA.—HEALTH RESORT (Inland Spa).—*Old-established increasing* PRACTICE (held over 20 years) on a *main line of rail* and in a healthy pleasant township much frequented by visitors in *the Season. Cash receipts average over £1,750 p.a.,* including several appts. One opponent. Price for house £1,250, to include furniture, instruments, and motor car (original cost £2,000), and for goodwill £1,250, part by instalments. Efficient introduction. A knowledge of Hydrology would be a big asset.
27. PARTNERSHIP.—*STAFFORDSHIRE.—LARGE TOWN.* — A *one-third* share is offered in a very sound old-established chiefly working-class *Practice, averaging* £3,700 p.a., including panel of nearly 5,000. Very suitable house, with 2 reception, 3 bedrooms, etc. Moderate rent. Premium only 1½ years' purchase, part by arrangement.
28. WORCS.—COUNTRY PRACTICE within easy reach of two good towns. Old-established, and averaging over £1,000 p.a., including panel of about 600. Fees 2/6 to 10/6. Good house, with ample accommodation. Rent on lease £85 p.a. Premium £1,350, £1,000 down, balance easy instalments.
29. SOMERSET.—Near Hospital Town, in very pleasant residential district, an old-established unopposed Country PRACTICE averaging over £900 p.a., including panel (producing about £400 p.a., with mileage and appts. Visits 3/6 to 21/-. Railway station in place. Nice house (5 bedrooms, dressing and bathroom, etc., garden). Price, freehold, £1,250, part on mortgage. Prem. £1,250, to include drugs, etc.
30. SOUTH-WEST OF ENGLAND.—POPULAR COAST TOWN.—A one-third share in an old-established PRACTICE, having good surgical scope. Gross cash receipts average £4,200. Panel of 1,800. Suitable house available, *on rental. Premium* £2,250.
31. PARTNERSHIP.—SOUTH COAST.—Favourite Residential and Holiday Resort.—A one-third share, with increase later, in a well-established non-dispensing chiefly better-class *Practice. Average income over* £3,000 p.a., with large scope. Fees 5/- to 21/-. Very little mid. Good corner house, with 4 *reception, 6 bedrooms,* etc. *Premium* 2 years' purchase. Scope for surgery.
32. SOUTH-WEST OF ENGLAND.—GOOD HOSPITAL TOWN.—A one-half share in an old-established mixed-class PRACTICE is offered owing to the retirement of the Junior Partner. Gross cash receipts average £2,300 p.a., including good appts. Small panel. *Low expenses.* Commodious house, with garden and garage, rent £70 p.a. Premium 2 years' purchase. Vendor on staff of Hospital, and scope for surgery.

Full Schedule of Terms and Conditions will be forwarded on application.

"EXPERIENTIA DOCET"

In an age when so-called enterprise is so frequently mistaken for real progress, it is well to remember that experience is the best impulse to sound progressive action.

Despite the "wonderful Cure-all Appliances" widely advertised to the public, the old-established

"HOUSE OF SALT"

prefers to link up its 137 years' surgical experience with the practical knowledge of the thousands of Practitioners it serves—always improving its designs according to current surgical practice and making its special productions to the prescription of those best qualified to order—

SCENE TYPICAL OF THE LIVES OF ANCIENT ARABIAN PIONEERS CARVED UPON A STELE.—In this illustration we see a man seated upon a chair resembling our folding-stools, and partaking of a meal set out upon a table. Before him stands a servant apparently bringing vessels containing food. To the left is a woman with what is believed to be a two-stringed musical instrument. The pre-Islamic Arabs were real pioneers of poetry and song, and loved the presence of harp and singing women at their meals.

BECKMAN'S TREATMENT IN General Practice

FEATURES OF THIS GREAT NEW WORK

Presents only treatment—the approved and proved therapy of to day.

Presents the latest and most thoroughly up-to-date discussion of treatment published—its newness is striking.

Constitutes an encyclopædia of modern therapy—not a smattering of ideas, but *all* accepted procedures.

Presents not only the views of one individual, but therapy as it has been evolved out of the experience of physicians all over the world.

The author has gone to the original sources for his material, often quoting verbatim from the work of those authorities whose names are identified with special work in this field.

The author, however, interpolates his own ideas based upon an intimate knowledge of modern pharmacology and an extensive and varied practice.

Recommends only therapy that has been proved in actual practice, and, in the case of the most recent measures, those procedures that have given promise of real value.

Does not attempt to hide behind the often heard words: "Upon this point we can say very little as the authorities are at present in disagreement." Even though particular forms of therapy are being challenged, Dr. Beckman nevertheless states the case of each as representing the best and most helpful treatment now available.

Goes into the most detailed presentation of dosage, prescriptions, and technique. No imagination is needed to understand just what Dr. Beckman means.

Presents those procedures such as the injection treatment of hæmorrhoids, varicose veins, etc., in greatest detail—every step of technique.

Offers not just one standard form of procedure such as the administration of a drug in certain dosage, but all forms and measures which others have found successful.

Presents therapy with fullness to permit individualization of treatment and the adaptation of the best possible form of therapy to the peculiar conditions presented by the individual case.

Gives all details of the treatment of all complications that may arise in any individual case.

Being individualized therapy, gives all details of the therapy, not only in adults but also in children, wherever the treatment of the child differs from that of the adult.

Has made extensive use of tables and charts to show at a glance what may be expected from the various measures described when tested in actual practice.

Gives the definite indications and contraindications for the use of all measures presented—it is safe as well as effective treatment.

Gives definite indications and contraindications for surgical interference where a disease offers the option of medicine or surgery, or when a medical case may become a surgical one.

Compares the effectiveness of each remedy in a given disease with that of all the other remedies as they are used in this particular disease.

By HARRY BECKMAN, M.D., Professor of Pharmacology at Marquette University, Milwaukee, Wisc.
Octavo of 900 pages. Cloth, 45s. net.

THE EXTRA PHARMACOPŒIA

By W. HARRISON MARTINDALE, Ph.D.

Nineteenth Edition.

Vol. I, 27/6 net; postage 6d.
Vol. II, 22/6 net; postage 4d.
Complete Work (2 Volumes) 50/- net, post free.

In Two Volumes.

Vol. I (1928) deals chiefly with Treatment, giving the important issues as to CLINICAL USE of all modern CHEMICALS and DRUGS, characters, dosage, methods of prescribing, etc.
Vol. II (1929) COMPLETES THE SET. It is concerned with INVESTIGATIONS, EXPERIMENTAL RESEARCH, DIAGNOSIS, and a large amount of new matter in medicine and allied sciences.

BRIT. MED. JOURN., Nov. 2nd, 1929, says: "*Has a well-established reputation as a most useful and convenient work of reference.*"
LANCET, Nov. 2nd, 1929, says: "*A clear and authoritative publication of the highest value.*"

An up-to-date Book for everything on the Therapeutic Use of Drugs. It embodies the Latest and Most Varied Information on Chemistry, Pharmacy, Therapy, and numerous other subjects

LONDON: H. K. LEWIS & CO. LTD., 136, Gower Street, W.C.1

JUST PUBLISHED. NEW EDITION. FULLY REVISED AND ENLARGED.

SECOND EDITION. Large 8vo. 280 pp. With 306 Original Illustrations, some of which are in colour. 21s. *net. Post.* 6d.

DEMONSTRATIONS OF PHYSICAL SIGNS IN CLINICAL SURGERY

By HAMILTON BAILEY, F.R.C.S.Eng., *Surgeon, Dudley Road Hospital, Birmingham.*

The Illustrations form the prominent feature of this volume, and much care has been taken to render them as accurately as possible. They have been still further improved and increased in number for this edition.

Lancet.—"It is time that a book of this nature was available in English. . . . The author is to be congratulated upon the success with which he has carried out his task. A feature of the book is the abundance of illustrations, all of which, in addition to the excellence of reproduction, are informative."
Brit. Jour. Surg.—"An admirable book which we can recommend to all students."
Edin. Med. Jour.—"*We have nothing but praise for this book,* which should be in the hands of every student entering upon his surgical course."

Bristol: JOHN WRIGHT & SONS Ltd. [Illustrated Catalogue free.] London: SIMPKIN MARSHALL Ltd.

METHODS AND USES OF

HYPNOSIS AND SELF-HYPNOSIS.

By Bernard Hollander, M.D. 6s.

Dr. Hollander's new book is the result of thirty years' experience of experimental hypnosis and hypnotic treatment, and contains directions how to apply hypnotism for the treatment of functional nervous and mental disorders and moral failings, as well as a survey of all that is scientifically known of this form of psychotherapy.

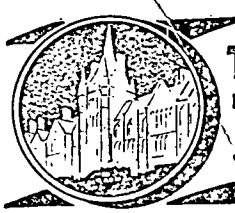
BY THE SAME AUTHOR.

THE PSYCHOLOGY OF MISCONDUCT, VICE, AND CRIME. *Third Impression.* 7s. 6d.

GEO. ALLEN & UNWIN, Ltd., Museum Street, London, W.C.1.

Greater Comfort for Your Patients.

"The Rose Corset-Belt"



which has set a new standard and proved so effectual in all abdominal cases where support is required. The X-rays have shown the actual uplift.

Each Corset-Belt is cut and fitted to individual requirements, and the patient is kept under observation until every satisfaction is given to both patient and doctor.

I have also invented an improved Colotomy Belt for both male and female patients.

My work is recommended by eminent members of the medical profession, and the following hospitals: St. Bartholomew's Hospital, Metropolitan, Charing Cross, Middlesex, London Temperance.

"MEDISUN"

ULTRA-VIOLET LIGHT APPARATUS

100% BRITISH.

Specification:

The "MEDISUN" Ultra-Violet Light Apparatus is of the quartz mercury vapour type. It has been so designed as to eliminate all unnecessary expense, and yet provide an efficient source of ultra-violet radiation, quick in its reaction speed, not requiring adjustment, and foolproof in its mechanical details. Whilst the price of the "Medisun" is quite low, its appearance is really first class. Manufactured in polished aluminium throughout, it does not require frequent cleaning, is designed to stand on any table, weighs only 14 lb., and is a thoroughly reliable piece of apparatus.

RUNNING COST:
30 TREATMENTS 3d.

Price:
For use on Direct Current ... £12
For use on Alternating Current £18
THIRTY OTHER TYPES

Intestinal Disinfection

BACILLUS COLI BACILLURIA AND URINARY INFECTIONS

CONDITIONS dependent upon infection of the urinary tract by *B. coli* are by no means uncommon, and present varying degrees of severity, from serious suppurative lesions of the kidney to mild bacilluria of little importance.

The mechanism of infection by *B. coli* in these cases is uncertain, but it may depend upon minute lesions of the mucous membrane of the bowel through which it passes, together with probably an increase in the numbers of a particular and more virulent type (hæmolytic varieties of *B. coli* are common in urinary infections in the male).

If, then, disinfection of the intestinal canal is accomplished, these forms are destroyed, and those already located in the urinary tract may be attacked by a urinary antiseptic. By the combined administration of Kerol, urotropin (hexamine) and acid sodium phosphate, the treatment of urinary infections by *B. coli* is placed on a rational basis, and many cases are cured by this line of treatment when they fail to yield to urotropin alone.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

A Remarkable advance in the presentation of H_2O_2

Also in exactly similar form and price—
SOLID IODINE

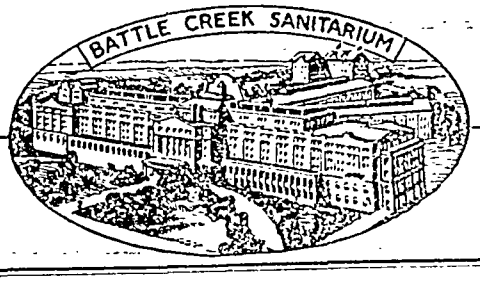
Owing to the rapidity in which H_2O_2 ordinarily loses its strength, it has not usually been practicable to carry a supply about without risk of frequent replacement; also, of course, of breakage.

Now a new process has been introduced of presenting Peroxide of Hydrogen in a solidified form, so as to enable it to be included conveniently in the physician's or surgeon's everyday case of instruments, etc.

This Solidified Peroxide of Hydrogen is known under the trade name of 'Peroxtik.' It is guaranteed to maintain its original 10-volume strength for a reasonable period.

A full-size tube of this new product will gladly be sent to the Medical Profession FREE on application to the Medical Dept., Messrs. ARTHUR H. COX & CO., LTD., 93, Lewes Road, Brighton, or can be purchased from the usual sources, at the cost of 1/3.

'Peroxtik'
SOLIDIFIED PEROXIDE OF HYDROGEN
in neat, handy glass tubes.



A special food for changing the intestinal flora

Lactose and Dextrin owe their value in changing the intestinal flora to the fact that they are more slowly absorbed than other carbohydrates. Because of this slow absorption they are able to reach the colon in sufficient quantity to cause a luxuriant growth of productive flora, thus keeping down putrefactive and poison-forming germs.

Lacto-Dextrin effectively disposes of the disadvantages of both Lactose and Dextrin in their crude form. It is a palatable and agreeable combination of the two, and is highly efficient in producing the growth and development of both B. acidophilus and B. bifidus in the colon.

Samples and literature will be sent on request to the Medical Profession on application to Sole Distributing Agents for U.K. and Irish Free State. COATES & COOPER. 41, Great Tower Street, London, E.C.3.

PEAT in the TREATMENT of SKIN DISEASES

THE effectiveness of the peat distillate principle in the treatment of skin diseases is sufficiently well known to need no comment. Sphagnol preparations contain this principle in a convenient medium. The medical soap, the ointment, the lotion, the suppositories allow of your using the properties of peat in the manner most suitable to the case in question.

The manufacturers make no more extravagant claim than this. They simply state that Sphagnol preparations provide the peat distillate principle in a convenient medium, and that they can be purchased for a reasonable price at any chemist's shop. They are prepared to submit samples for you to judge their claims. If you are a medical practitioner simply write to Peat Products (Sphagnol) Ltd. (Dept. B21), 21, Bush Lane, London, E.C.4.

FOOD POISONING—
THE KAYLENE TREATMENT

The following letter has been received recently.

MESSRS. KAYLENE, LTD. April 17th, 1929.

DEAR SIRS,

I am in receipt of your sample of Kaylene, for which I thank you. I do not dispense and do not wish to be without some in the house.

My last sample was used on a patient suffering from acute Ptomaine poisoning following a meal of shell fish (mussel) at 10.30 p.m. Symptoms first appeared at 12.30 a.m., and when I saw him at 3.0 a.m. he was vomiting blood and passing almost pure blood per rectum. He had commenced cramps and nervous twitchings which would shortly have gone on to tonic convulsions. He was very collapsed and had a weak pulse. I gave him only Kaylene in cold water, one drachm every quarter of an hour, from 3.0 until 8.0 a.m., when I felt it safe to leave him. For the next two days Kaylene was given every one to two hours, and was then followed by Kaylene-ol. No other medication of any sort was used, and he made an excellent recovery. This follows a somewhat similar case which I treated at the end of last year.

Your excellent preparation should supplant Bismuth for any purpose.

Yours faithfully;

Physician to ———. ——, M.B.

RADIO-MALT

In Preventive Medicine

The curve representing the incidence of disease rises annually during winter; in former years the graph was steep and the peak was high. Since the recognition of the importance of preventive medicine, however, the picture has changed, and both the toll of life and the handicap to industry have decreased considerably.

Radio-Malt, on account of its proved anti-infective property, is of the utmost service in this campaign against illness. Physicians now realise the importance of the timely regular administration of Radio-Malt, on a wholesale scale, to children and adults—to the healthy as well as to the sick.

In Radio-Malt Vitamins A, B_1, B_2 and D are present in scientifically calculated and standardised quantities; literature describing this unique body-building and health-preserving vitamin product will be forwarded to any member of the medical profession on application.

THE BRITISH DRUG HOUSES LTD. LONDON N-1

Vit. Pr 35

Intestinal Stasis and B Vitamin.

Co. 76.—Within a week I was able to do without the usual mild saline aperient. ——, M.B., F.R.C.P.

Co. 98.—In my case, the relief of intestinal stasis was immediate. ——, M.B.

Co. 120.—I have prescribed Bemax extensively. Undoubtedly constipation is helped, rheumatism also. ——, M.B.

Amongst hundreds of letters received from medical men endorsing the value of BEMAX as a tonic restorative food, no comments occur more frequently than those recording its beneficial results in constipation.

Laboratory researches have clearly demonstrated that one of the first results of a B Vitamin deficient dietary is a general deterioration of the muscular and nervous intestinal reaction, which becomes progressively more serious so long as the deficiency is unremedied.

In view of the general deficiency of Vitamin B in the normal diet of to-day, the high incidence of Intestinal Stasis and other Digestive Disorders is not surprising, but it is gratifying to notice so unanimous an opinion that the restoration of Vitamin B, in the form of BEMAX, to the normal dietary, does in fact bring marked relief from symptoms for which other causes have often been assigned.

BEMAX contains a higher proportion of natural Vitamin B than any other known substance. It is prepared from the living embryo of selected cereals. It is rich in Vitamins A and E, and contains valuable mineral salts.

Laboratory reports on BEMAX and a sample tin for personal trial will be sent to any medical man on receipt of his professional card.

S.U.P. 36

In Influenza

A booklet entitled "S.U.P. 36 in the treatment of Influenza" has been posted recently to members of the medical profession; this publication contains an account of special clinical tests carried out with S.U.P. 36 during the influenza epidemic of 1929. The reports quoted prove conclusively the very real value of intramuscular injections of S.U.P. 36 in the treatment of influenza.

Any physician who has not received a copy of this interesting booklet is invited to apply for one. There is also available literature describing the use of S.U.P. 36 in a number of other inflammatory conditions in which there is marked pyrexia.

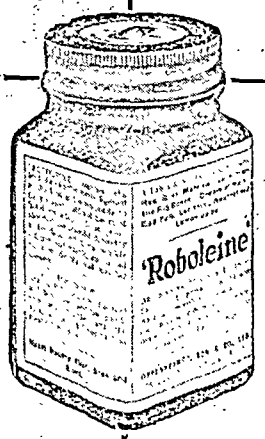
THE BRITISH DRUG HOUSES LTD. LONDON N-1

S.U.P. 36 13

If your patient must stop sugar

It is well known to the Medical Profession that a child's craving for sweets is natural, as a child requires a large supply of an easily assimilated hydrocarbon. Unfortunately ordinary sugar upsets the digestive functions of some children, and "glucose," recommended in its place, is too often of unknown composition and too expensive.

The monosaccharides of fruit-sugar offer obvious advantages over the di-saccharide, sucrose, and a pure and very palatable mixture of dextrose and lævulose is now available under the trade name of SUNNYCOMB.



SUNNYCOMB was first made at the request of some members of the Medical Profession who desired a reasonably cheap monosaccharide for sweetening baby-food for babies who were not flourishing. The results were so satisfactory, and the product so palatable to both young and old, that it was decided to make it generally available.

SUNNYCOMB supplies the necessary carbohydrates in an easily digestible form, being so readily assimilated that it does not upset the digestive functions as ordinary sugar sometimes does, yet it is at the same time a pleasing and appetising delicacy.

SUNNYCOMB is made by Macfie & Sons, Limited, who first started in 1763 and have been sugar refiners in Liverpool continuously since 1837. They guarantee it to be a pure wholesome product and will willingly supply free samples and full information about it to any member of the Medical Profession on receipt of a postcard.

Successful Treatment of Hyperchlorhydria and Associated Conditions

"Alocol" (Colloidal Hydroxide of Aluminium) has proved remarkably successful in the treatment of hyperchlorhydria, gastric ulcer, fermentative dyspepsias with gastro-intestinal flatulence, acid eructation and other symptoms common to gastric disease.

The advantages of "Alocol" are that it actually removes from the system the causative acid radicle (Cl) instead of merely neutralising it, and so permitting reabsorption, accumulation and consequent recurrence of the symptoms of the disease.

Furthermore, "Alocol" neither hinders proteolysis nor causes destruction of any food element or factor. "Alocol" has a distinct healing and sedative effect; it promptly allays irritation by absorbing acid and other irritants.

Complete chemical history of "Alocol" with convincing clinical reports and supply for trial, sent free to physicians on request.

ORIGINATED NEARLY A CENTURY AGO . . . THE MEDICAL PROFESSION HAS ADOPTED THEM EVER SINCE

BRAND'S Essences were first made by Mr. Brand and a famous doctor in 1832. Since that time, they have been the standby of the Medical profession.

Rich in phosphates and the stimulating properties of meat, Brand's Essences are invaluable for all states of exhaustion and during convalescence When patients are listless and reluctant to eat, a diet of Brand's Essence will bring back the appetite and induce them to take more solid food.

Brand's Meat Essences have a stimulating action on the gastric juices and can be rapidly absorbed without strains on the digestive organs.

They are the pure juices of meats extracted by an exclusive method and sterilized by heat processes under scientific supervision.

Brand's Essences (Beef, Mutton and Chicken) can be obtained at chemists and stores throughout the world in small and large-sized tins and jars. Brand & Co. Ltd., Mayfair Works, South Lambeth Road, London, S.W.8.

The experience of thirty-eight years confirms its value in

Phthisis

Angier's Emulsion pacifies the irritable stomach and intestines, and renders them docile, receptive, and retentive of food and medicine. It relieves the symptoms of digestive disturbance which are almost constantly present in Phthisis, and which constitute an insuperable barrier to proper nourishment and medication.

Angier's Emulsion facilitates, hastens and completes the processes of digestion and assimilation, so that the patient is enabled to take sufficient nourishing food. It is a strengthener and vitaliser to the body, fortifying its disease-resisting powers by increasing the absorption of nutrient material, and it acts as an anti-bacillary agent, inhibiting the growth of disease-producing bacteria and their toxins.

Angier's Emulsion has a specific palliative influence on the symptoms of Phthisis—fever, night-sweats, cough, expectoration, and exhaustion are ameliorated, and the life of the patient made more comfortable, more free from distressing symptoms. In most cases of Phthisis the use of Angier's Emulsion obviates the necessity of administering depressing and narcotising cough sedatives.

Angier's Emulsion is the most palatable of all emulsions, and is easily tolerated by delicate stomachs. It has no deleterious influence upon any function of the body, and it is taken by the patient with pleasure. In the advanced stage of Phthisis, the agreeable, soothing qualities of the Emulsion are especially appreciated, and invariably afford much relief to the sufferer.

Angier's Emulsion should always be specified when prescribing petroleum emulsion; otherwise some disappointing imitation made with ordinary petroleum may be supplied.

NATURALLY RICH IN VITAMIN "D"

THE DANGERS OF HYPERVITAMINOSIS

Damage from irradiated ergosterol

"An infant whose birth was retarded two weeks, and whose initial weight was 4,500 g., became weak soon after being born. He had vomiting, a certain rigidity of the skin, and a sub-febrile evening temperature; the Pirquet reaction was negative. Though no symptoms of rickets were present, 6 drops of irradiated ergosterol were administered daily beginning in the tenth week, and this dose was continued for 96 days. Seventy days after the beginning of the treatment, leucocytes and albumin were found in the urine, but were ascribed to cystitis. The child died when 5½ months old, and the post-mortem examination, as reported by Dr. Puschler, in the 'Zeitschrift für Kinderheilkunde,' showed severe calcification of the tubules and interstitial tissue of the kidneys. The administration of irradiated ergosterol seems to have caused this condition, which corresponds with what is found in animals fed in the same way. The case suggests that this substance is by no means harmless if given to infants not suffering from rickets."

The above extract from *The Lancet* (January 4th, 1930, p. 42)

shows only too clearly the grave danger attending the addition of irradiated ergosterol to infant foods. This practice originated in an abortive attempt to improve the nutritive value of milk produced on soils deficient in their vital mineral constituent. It is now known, however, that even the natural vitamin D content of milk is not efficient unless the calcium content is also adequate, and any attempt to improve the nutritive properties of a milk by the addition of a synthetic concentrate, the potency of which is unknown and dangerous, is futile in the absence of the vital calcium salts.

Cow & Gate Milk Food

"Cows' milk made safe and suitable for Baby."

Cow and Gate is produced from the milk of the renowned pastures of Somerset and Dorset. Unlike the sun-scorched grass of other climates, where cattle suffer from calcium deficiency and the resulting Osteophagia and will eat the bones of their own kind to rectify this, these pastures provide fully for the mineral requirements of the cows and the milk they produce. This milk contains an adequate vitamin content for the full assimilation of the mineral salts which are preserved undisturbed by the specially designed and Improved Roller Process. For these reasons the makers of Cow and Gate do not add to their products concentrates whose action is uncertain and by demonstration dangerous.

The makers will gladly supply samples for clinical test and any further information required, and wish to remind Members of the Medical and Nursing Professions that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

COW & GATE, LTD.

GUILDFORD

FOR NASAL AND ORAL HYGIENE

NASOTONE BRAND PREPARATIONS

FOR COLDS, CATARRHAL CONDITIONS, INFLUENZA, AND HAY FEVER

NASOTONE CREAM

A soothing and antiseptic nasal cream containing Thymol, Menthol, Phenol, and Boric Acid in a pleasantly perfumed paraffin base.

NASOTONE CREAM is of the greatest value in dispersing the congestion and stuffiness arising from Nasal Catarrh, and destroying the germs which cause infection. The cream is introduced directly into the nostrils by means of a special nozzle attached to the tube. Inside the nostrils the cream is warmed to its melting point, thus setting free the curative vapours of the Menthol, Thymol and Phenol, and imparting its antiseptic properties to the mucus that bathes the membrane.

NASOTONE VAPOUR

NASOTONE VAPOUR is a scientific blend of antiseptic aromatic oils possessing high germicidal value

Used on the handkerchief as an inhalant it clears the head and renders breathing easy, and when used in the early stages of a cold will be found to abort the attack. Its antiseptic properties are lasting and effective for many hours. It is supplied in neat sprinkler flasks which may be conveniently carried in the pocket or handbag.

NASOTONE SPRAY

A pleasant and effective combination of Thymol, Menthol and Camphor with Essential Oil of Cinnamon in a petroleum base.

Especially recommended as a routine application for the nose and throat. Used in the morning it forms a valuable safeguard during the day against sore throat and the common cold. It is also an effective treatment for Colds, Catarrh, Tonsillitis, Laryngitis and Hay Fever, and should be used as soon as symptoms appear.

NASOTONE SPRAY should be sprayed into the nostrils and throat by means of a suitable atomiser.

An Address
ON
MATERNAL MORTALITY.*

BY
DAME LOUISE McILROY, D.B.E., M.D., D.Sc.GLAS.,
PROFESSOR OF OBSTETRICS AND GYNAECOLOGY, UNIVERSITY OF LONDON, ROYAL FREE HOSPITAL.

THE problems in the causation of maternal mortality have been so much before the profession and public that I feel I have little to contribute that is new except the results of my own experience. We are all trying to find an explanation for the stationary, if not increasing, maternal death rate, and we are to some extent groping in the dark. I shall limit myself more or less to the obstetrical rather than the administrative aspect of the problem.

Two recent publications have appeared and have given us much material for discussion—Dr. Kinloch's report (Scottish Board of Health, 1929) on the maternal death rate in Aberdeen, and the Government report of the Midwives Committee.[1] We are awaiting with much interest the Government report of the Committee on Maternal Mortality.

On page 7 of the report on midwives the following statement appears: "In spite of all efforts to lessen the death rate amongst women in childbirth, the position is now little better in this respect than it was twenty years ago." This committee has endeavoured by its suggestions to fit the midwife into a scheme on a broad and national basis for the reduction of maternal mortality. We can never be Utopian enough to hope to eliminate deaths from childbirth, but we can reduce them considerably. This is the faith of all of those who are concerned with maternal welfare. If over 27,000 women lost their lives in England and Wales in the last ten years because of pregnancy or childbirth, we cannot but feel that some of these deaths were due to inadequate treatment of the patient. We must be muddling our prevention somewhere. It is not only the death rate we are concerned with, but the enormous amount of ill-health among women which is due to unskilled handling during pregnancy and childbirth. The morbidity alone should be a reason for energetic research. Some day gynaecological beds will diminish in numbers as maternity beds increase. If the maternal death rate has not decreased in the present century what are the outstanding factors to be considered in the changes which have taken place in midwifery practice? These are mainly the increase in the institutional treatment of patients, the establishment of ante-natal clinics, the introduction of panel practice, and the training of midwives.

Institutional Treatment.

The increase in the number of maternity beds throughout the country, especially since the war, has been a marked feature of the present century. There is a great demand for a further increase because of the difficulties of housing.

Dr. Kinloch's report—the result of the most careful research and courageous conclusions on the part of him and his staff, which includes Dr. Steven—is sad reading. In Scotland the maternal death rate in 1928 was 7 per 1,000, and sepsis accounted for 2.4 per 1,000 of these patients. During the preceding ten years the rate was 6.4. An analysis of the sources of the deaths in the Aberdeen area shows that in the practice of midwives the deaths were 2.8 per 1,000, among practitioners 6.9, while in institutions the death rate was 14.9.

If such a result of hospital treatment applies to other maternity institutions we would all feel it was time for us to dispense with the segregation of obstetrical patients and have them treated in their own homes, preferably by midwives only. But this is not the general mortality rate of hospitals, and presently I will show a less gloomy result from the Royal Free Hospital. It may be a good thing to make the worst of it in order to make the best of it. We must, however, have made some progress in hospital practice in all the years we have struggled to conform to the best surgical methods of cleanliness and asepsis. It may be, perhaps, that surgery has been more of a danger than a blessing, especially if practised by inexperienced obstetricians. In the past no doubt many maternal deaths from puerperal sepsis were not registered as being due to childbirth. Now these deaths are being properly investigated, as in the year 1928 in Aberdeen. The mortality rate may even be increased all over the country because of more efficient registration. There must be less sepsis than in the days when a friendly neighbour supervised the confinement and a doctor was called in who had little knowledge of the researches of Lister or Pasteur. Civilization no doubt increases the risks of parturition. Mental development, we are told, means increase in the size of heads while no corresponding increase in pelvic measurements has been observed. This may in time tend to increase disproportion.

Dr. Kinloch explains the cause of sepsis as due to contagion in hospitals and to carriers in the medical profession. The midwife, because of her special work and strict regulations, is less likely to be a carrier. He considers more cubic space should be given to patients in hospitals and fewer numbers admitted. His report is very encouraging with regard to ante-natal care. Dr. Kinloch is of the opinion that 90 per cent. of the cases of puerperal sepsis are due to the haemolytic streptococcus, and that early notification and treatment will prove of great value.

Dr. Jellett, in his recent book on the *Cause and Prevention of Maternal Mortality* (Churchill, 1929), writes from New Zealand and gives many explanations of the problem. He states that in the Rotunda Hospital, Dublin, during the five years preceding 1893, the death rate was 3.1 per 1,000. He states that, while asepsis was unknown, intervention during labour was limited. At present intervention is frequent and asepsis occasional. In the future it will be necessary to avoid intervention as far as is possible, and asepsis must be positive. He considers knowledge, skill, and suitable environment to be essential.

In the obstetrical unit in the Royal Free Hospital the maternal death rate for the last eight years is 2.7 per 1,000. The chief causes of death are obstetric shock, including haemorrhage (10 cases), and sepsis (6 cases, all of which were operative cases). Toxaemia was accountable for 4 cases, embolus for 2, broncho-pneumonia for 1, heart disease for 1, and acute suppurative appendix for 1.

The value of ante-natal care is proved by the small number of cases of accidental or toxaemic haemorrhage which now occur in hospital practice.

Sepsis and its Prevention.

It is essential, when possible, that all cases of sepsis should be treated in the isolation wards of maternity hospitals. Much valuable experience is gained by the obstetrical staff in the treatment of sepsis, and students are more easily impressed with the necessity for preventive measures against sepsis when they see the results of its attacks.

The avoidance of contagion is essential. Attendants should not suffer from carious teeth or septic tonsils. But the most common source of infection is the patient herself. Precautions against sepsis are taken in every case, and yet a normal patient dies, and another, after a serious intervention, has an afebrile puerperium. A parallel example is found in deaths from the sting of insects.

Attention to general health during pregnancy will help to prevent sepsis, especially if carious teeth and any other focus of infection are treated. Coitus is a not infrequent source of infection, and should not take place within two months of term.

The vaginal bacillus of Döderlein, when present, is an important factor in preventing sepsis. If this bacillus is absent, or if pathological germs are present in the ante-natal period, vaginal pessaries of 1 per cent. lactic acid encourage the growth of Döderlein's bacillus.

On admission to hospital a patient ought to be cleansed in a special receiving room. Dr. Jellett strongly deprecates the use of the sitting bath, as it conveys sepsis to the vulva and vagina. The patient's, when washed, should be shaved, and the vulva washed and disinfected with biniodide or other solutions. Swabbing out of the vagina or douching is not necessary and is dangerous, even in

* Delivered to the Glasgow and West of Scotland Branch of the British Medical Association, October 25th, 1929.

operative cases, unless a definite septic condition is present. An electric hair drier is a great convenience in a receiving room.

As to antiseptics in labour, they all have their day. Acroflavine is the one I prefer, but biniodide is hard to beat. "Blue paint" has its followers, but an antiseptic which stains the linen and remains on the skin until after the patient returns home does not appeal to the aesthetic sense of most women.

Nurses or assistants should not scrub their hands with brushes and strong antiseptics. Abrasions and cracks of the skin are the result, and these may become septic, especially in winter time. Swabs of wool in ethereal soap solution are the best means of cleansing the hands or the vulva of the patients; this is followed by biniodide alcohol solution. Gloves should be dry when ready to wear. Dr. Lachlan Grant has pointed out the advantages in domestic practice of washing in water running from a tap.

Vaginal examinations should be quite unnecessary in normal cases which have had ante-natal supervision and where abdominal methods of diagnosis are efficient. Vaginal examinations are a source of sepsis, and are only required when other methods of diagnosis have failed or where some emergency, like sudden failure of the foetal heart, suggests prolapse of the cord. If an examination is made as a routine, it is safer before the membranes rupture, although prolapse of the cord occurs after rupture. It has always seemed to me a pity that vaginal examinations should be insisted upon in the training of pupil midwives. The rules were made before ante-natal examinations came into use. I am glad to see, on page 92 of the Midwives Report, that there is a suggestion for the modification of this rule. Students should be taught to make their diagnosis of a presentation before labour begins, if possible. The position, fixation, and descent of the head can be ascertained in the average case by external palpation. In the unit labour wards of the Royal Free Hospital a student may only make a vaginal examination in the presence of a member of the staff, and the time and the result must be carefully recorded in the case sheet. As few examinations as possible are made, and in some cases they are omitted entirely.

Rectal Examination.—Dr. Jellett lays stress upon the advantages of this. Some time ago, for a period of eighteen months, we tried rectal examinations. The sepsis rate was increased rather than diminished in that period of time. I think it is an objectionable method of examination. The patients dislike it. It causes pain if the head is low or if haemorrhoids or oedema are present. If the rectum has cracks or sores the risk is increased. The finger in the rectum tends to push up the posterior lower vaginal wall and infect the cervix. It is difficult to diagnose the degree of dilatation of the cervix, the presenting part if a caput is present, and also to feel a prolapsed cord if pulseless. Can we trust every student and midwife to see that the gloves are sterilized after a rectal examination before using them for delivery?

In the third stage of labour the patient should lie on one her back and so prevent the entrance of air and m[illegible] organisms into the uterus because of the apposition[illegible] anterior and posterior vaginal walls. The ute[illegible] left alone, as manipulations upon be[illegible] tend to cause suction [illegible] cervix from the vagina, [illegible] with the walls and [illegible] and lacerations shou[illegible] septic organisms. [illegible] carefully sought for, [illegible]

During the puerp[illegible] who does not change [illegible] I almost think it would [illegible] own washing up. Bed[illegible] of infection, as they are [illegible] the ward, and are only di[illegible] innocuous disinfectant. Ea[illegible] bedpan in her locker. Afte[illegible] in an ever-boiling cauldron o[illegible] be disinfected before a new p[illegible] would be better if bedpans co[illegible]

much as possible, and patients encouraged to get out of bed; they are very much disliked by working-class women. If a lacerated perineum does not heal, the stitches should be removed and antiseptics applied. If healing is slow, scarlet red ointment for a few days has a stimulating effect. When clean, secondary suturing of the freshened edges in about ten days gives excellent results. Tightly applied vulvar pads and binders prevent proper uterine drainage. It is difficult to persuade women that this traditional method has its disadvantages, if not dangers.

Treatment of Sepsis.

This subject is too long and too controversial for discussion. Early isolation and treatment is essential. In acute cases the treatment comprises nursing in the open-air ward, daily colon lavage, antistreptococcus serum 20–40 c.cm. in a daily dose, quinine hydrochloride 5–10 grains daily into the buttock, and blood transfusion. Drainage of the uterus by glycerin also helps in acute blood infections, but it is more beneficial in localized sepsis. Douching of the uterus and hysterectomy have been entirely given up by me. Instrumental curettage seems to be an obsolete operation in Britain. Sometimes a piece of retained placenta may have to be removed later, but, as a rule, glycerin causes the uterus to expel it spontaneously.

Abortion, especially when criminally induced, is an increasing cause of maternal mortality. It accounts for many gynaecological affections and may cause sepsis at a subsequent confinement. If the placenta is retained and offensive, it should not be removed until the patient's resistance is raised, as there is grave danger of disseminating septic emboli and organisms into the blood stream. Glycerin drainage, serum, and quinine should be employed in acute cases. The placenta can be removed in a few days, if not expelled spontaneously. Since employing this method of treatment we have not lost a case of septic abortion, even in patients where perforation has been suspected. It is a mistake to perform hysterectomy in these cases of criminal septic abortion except later on, if injury to the uterus is known to have taken place. Intervention, other than drainage, is the cause of some deaths from sepsis. Criminal abortion requires investigation, and is a serious cause of the increase in maternal deaths, more especially in Continental countries. I have advocated for some years the notification of all abortions, just as stillbirths are notifiable.

Toxaemia.

Ante-partum haemorrhage, due to toxaemia, is now very rarely met with among patients who have had ante-natal care. Eclampsia has decreased. Fulminating types of eclampsia occur in spite of any preventive treatment. The death rate from eclampsia has much decreased because of the use of the Tweedy-Stroganoff treatment and the decline in Caesarean section, and also because of the abandonment of accouchement forcé. Maternal deaths in cases of toxaemia [illegible] get work. [illegible] cine and surgery they would be of additional value in looking after medical or surgical complications, and their relationship to the practitioner would be more easily defined. Registration with a doctor of an expectant mother would ensure that the midwife has prompt assistance if required at labour. Many midwives undergo great anxiety because medical help is unobtainable; I have known of cases where four or five doctors have been sent for before one could be found or induced to attend. I have always expressed the opinion that midwives should be inspected by senior members of their own profession and not by women doctors. If a doctor is employed, he or she should be allowed to carry out treatment if required, and not merely report on the conditions found.

Finance is the greatest problem of all, both in public health and in private practice. The public must learn that if they want efficiency this has got to be paid for. It is for us to point out the way and let those concerned find the financial support.

We look forward to a new era now that the advice and help of the obstetricians of the country is available as a corporate body—namely, the College of Obstetrics and

sleep," or adaline in 10 grain doses by the mouth. Sedatives and intermittent anaesthesia should be used for the second stage. It will be found that the dose of morphine can be reduced and its effect prolonged by dissolving it in a 50 per cent. solution of magnesium sulphate and giving intramuscularly. Gas and oxygen is the best anaesthetic for the mother and least harmful to the foetus. Indeed, the oxygen is beneficial if the nitrous oxide gas is removed and the oxygen continued after delivery and before the cord is severed in cases of blue asphyxia. Deep anaesthesia should be employed for the delivery of the head. Midwives, who attend 60 to 70 per cent. of the cases in the country, should be taught the use of sedatives in labour under the supervision of the doctor with whom the patient is registered as an ante-natal case. In our unit nearly every patient is given a sedative, and quite a number are given anaesthetics, apart from those who have operative intervention. Patients must be prepared to pay for an anaesthetist in private practice, just as they pay for a surgical operation. Nothing is too good in the way of skilled help for a woman who is bringing a child into the world.

Embolus is the nightmare of all obstetricians. It is due to sepsis in most cases. Exercises during the puerperium and drainage of the uterus by sitting up in bed all help in its prevention.

Caesarean Section.

The Caesarean section rate in the unit in eight years is 1.6 per cent. with a death rate of 3.9 per cent. This is about the average mortality of the teaching hospitals in Britain. Professor Whitridge Williams, quoted by Jellett, gives his hospital rate as 3.35 per cent. when he excludes deaths from general conditions. He estimates the general death rate in the United States as about 10 per cent. Dr. Jellett gives the general mortality rate in the most favourable circumstances as 2 per cent. In unfavourable conditions it is 10 to 50 per cent. Caesarean section has its uses and its risks. So far as possible it should never be a substitute for natural labour. In some small institutions it is performed by a general surgeon who has little experience of obstetrical methods and who only undertakes the case because of its surgical aspect. It is an operation which appeals to everyone, as it takes under thirty minutes to perform, as compared with the possibility of a labour of as many hours. It is an easy way out of the difficulty when in doubt. The Caesarean section rate has been reduced since we began to operate only when the patient had been in labour for a few hours. A considerable number of patients deliver themselves in a most unexpected manner when it has been decided beforehand that Caesarean section may be necessary. In cases where Caesarean section has been definitely decided upon it is better to wait until labour has started, as there is less risk of haemorrhage, owing to better uterine contractions. The partially dilated cervix gives better drainage. Caesarean section after prolonged labour, when the patient [illegible] menstrual period [illegible] has enquired about. It is remarkable how definite the majority of patients are on this point; this is fortunate, as the period of amenorrhoea still constitutes the most exact method we have of estimating the approximate date of confinement. The history of previous pregnancies and labours (if any) is also of great value. If one patient says that in the previous pregnancy the legs and face became very swollen, it would indicate the necessity for a very strict examination of the urine, while if another reports that, of several previous pregnancies, only one child is alive, the others being born dead after prolonged labours with instruments, a careful examination of the relative size of head and pelvis would be indicated. In the primigravida, of course, we have no previous history to guide us, and we have to form our own opinion from the beginning.

Other points to be inquired about are the condition of the bowels. Most women suffer from more or less constipation, and this has to be borne in mind when advising the patient about her habits. It has to be emphasized that if a satisfactory daily motion of the bowels is obtained, the likelihood of toxaemia or eclampsia is remote. The amount

* A paper read before the South-West Wales Division of the British Medical Association at Carmarthen, December 18th, 1929.

Obstetrics in Dublin last April the opinion was unanimously expressed that forceps should not be applied unless the head was close to the pelvic outlet. High forceps have no longer a place in obstetrics. "Failed forceps" means that they should never have been attempted. The risk of sepsis and lacerations is increased by the use of forceps, not to mention the great danger to the foetal head. Substitutes for forceps, or, rather, the prevention of their use, are to be found in the employment of frequent hot sitz-baths before and during labour and the administration of sedatives. I have found that the squatting position in the second stage helps to drive the head downwards. If the foetus gives signs of distress, forceps should not be applied until the results are observed of giving the mother a hypodermic injection of 3 grains of camphor. This stimulates the foetal heart and enables it to bear better the stress of labour.

Students should be taught not so much the indications for forceps applications as their risks, and also what can be done to avoid them. The blades are often badly applied, and the newborn may carry a groove over its forehead or in the neighbourhood of the eye for some hours after birth. Neo-natal deaths or subsequent cranial complications owe, in many cases, their origin to maladjustment of the blades. This would prove a valuable field of research for infant welfare clinics and school inspection. Each blade should be applied so that the ear lies in the centre. The head should be as completely flexed as possible, as it is only the suboccipito-bregmatic diameter which can bear the pressure with the least injury on its way through the pelvis. Manual rotation of an occipito-posterior position will save many a case from forceps, as it does from craniotomy. Slow delivery, with relaxation between the pains, helps to prevent undue pressure from the blades. The midwife should not expect a doctor to apply forceps in every case of delay in labour in which she has sought his aid. Patients' relatives should not object to the doctor's full fee on the score that no forceps were applied. There is always a temptation on the part of a busy practitioner "to get the case over," and at the same time to relieve the suffering of the patient and the anxiety of the relatives. If the patient is under the influence of sedatives the demand for forceps is less pronounced. Dr. Jellett quotes a case where Sir William Smiley was asked by an anxious husband if he could not do anything to relieve his wife. Sir William gave the characteristic reply, "Yes, mischief!"

Pituitrin is given in labour more extensively in private practice than in hospital. It should only be used when the head is on the perineum and delivery has been delayed because of weak pains. It must be remembered that a dose of pituitrin given before delivery inhibits the effect of a subsequent dose which may be required for post-partum haemorrhage after the third stage is over. Labour is always more easily borne if its aesthetic aspect is considered. The first stage should be spent in a room other than the delivery room, which in private practice is usually overheated and smells of antiseptics and airing baby clothes. In the new Royal Free Hospital building, we have planned to have a waiting room where the patient [illegible] about and pass the time with magazines, etc., until even in [illegible] progressed. A second room is provided for the pregnant accordi[illegible]

a patient with, let us[illegible] three[illegible] will show the uterus enlarged to the [illegible] five months—and while in the majorit[illegible]ision is one of the discrepancy is due to an error in the [illegible]ry practice. But if all is normal here [illegible] to attend an ante-natal should be taken *and should be*[illegible] doctor. I consider ante- intercrestal, external, and d[illegible]anch of obstetrics. In all taken with an ordinary pelvi[illegible] clinics in connexion with and from the two last the tri[illegible]t clinics, however, are under It is very useful to take al[illegible]

the public health authority. The staffing of these clinics is carried out in some cities by whole-time medical officers with a special knowledge of obstetrics. These medical officers attend when summoned by the midwife for complications of labour. This arrangement is found to work so well that it is being extended to more towns. This work is, of course, restricted to the poor patients. In most areas, however, the clinics are staffed by part-time practitioners who may, or may not, be engaged in the practice of midwifery and may have little actual experience of labour and its complications. It may be impossible for them to follow up a case, especially if they do not reside in the district. These practitioners cannot be expected to take the whole responsibility of the case, and they tend to become critics of the doctors or midwives who attend the confinement. The local practitioners called in at the confinement take no responsibility for the complications, which could have been avoided by more efficient ante-natal examinations. They in turn become critics of the methods of the clinic, and the poor patient is thus the loser. It is a wrong system altogether, but it will take time to make any suitable readjustment. The practitioner who does the ante-natal work should supervise, if necessary, the labour and puerperium, and should be made responsible for the whole welfare of the patient with the midwife. It therefore means that the patients must be under a whole-time medical officer or under the general practitioners in the locality. In rural districts the patients can visit the doctor or midwife or be visited in their homes, as the case may be. Ante-natal centres are obviously more difficult to arrange in country districts than infant welfare clinics, nor are they necessary if the work can be done individually. In theory it seems ideal that the local practitioners, or those of them who have an aptitude for midwifery, should do the work. But we have to reckon in some cases with professional ill feeling where a family practice is thus acquired by one who is not bound by the rules of etiquette of the specialist. Much as the whole-time officer or one from outside the district may be criticized, he or she is at least a non-competitor in family practice.

It is stated occasionally that the general practitioner has little knowledge of ante-natal work. This can be remedied by post-graduate courses, especially of an intensive kind. But the new generation of practitioners and assistants has a good knowledge of ante-natal diagnosis and treatment as it is taught in hospital. They mean to exercise this knowledge in practice. Ante-natal examinations should be paid for in addition to the fee for a confinement.

General Practitioner or Specialist?

Some specialists take the view that midwifery should be in the hands of specialists and midwives. This cannot apply to anything but large towns and to hospitals; in smaller areas it is impracticable. There is no doubt that the general practitioner has lost a considerable amount of his midwifery practice in the last ten years. Some of the patients go to hospitals, some to specialists, but since the war the main midwifery among the working classes has been undertaken by the midwife. The panel system may have an influence upon this diminution of practice. If the general practitioner has relinquished so much midwifery practice he cannot be held responsible for the stationary mortality. Trained midwives have in a large measure helped in its decrease, and yet we cannot find a solution of the problem. There is much to be said for the family doctor who undertakes midwifery. He knows the homes and circumstances of his individual patients. This is a knowledge which a specialist cannot acquire first-hand. The practitioner has perhaps treated the mother for conditions pre-existing to pregnancy. He is trusted and is easy of access. He can follow up the progress of the health of the mother and the welfare of her child. Continuity of supervision is the aim of all health authorities, and nowhere can this be so well attained as by the supervision of the local practitioners and midwives.

From the point of view of a teacher of midwifery the role of the general practitioner is of very great importance to me. How very few students specialize in midwifery compared with the large number who go into general practice. Specialists are not born, but are made by their post-graduate studies. If we are to become teachers of a particular type of student, I consider it would be waste of time and money on the part of medical schools if midwifery were taught and not practised by their graduates. Why, our whole aim is to train our students in the best way possible to fit them to be efficient in midwifery of the domestic practice. The bulk of the midwifery of the country—among the middle classes at least—must be in the hands of the family practitioner, who should be well trained and willing to undertake it. The employment of a consultant is a different matter, and should always be available when possible. In outlying districts, where the mortality is still high because of the absence of skilled and prompt assistance, the specialist is out of the question for at least 50 per cent. of the population.

The training of students has been most deficient in clinical obstetrics, especially with regard to attendance on normal labour. Operations are demonstrated by the senior staff which will never be done by the average practitioner, whilst ordinary cases are either taken under the supervision of a midwife or alone. If there is a slight complication, a house-surgeon undertakes the demonstration of the case. Many students conduct only about six or eight cases out of the twenty laid down by the regulations of the General Medical Council. If a placenta is seen being expelled, that counts as "a case," or even if its expulsion is observed from a distance that is sufficient. Students should be signed up by the senior staff for work done and not for the number of cases attended. In our unit the students must deliver the patient completely before it is counted as a case; if delivered by forceps or by other operative methods by the staff it is not counted. Pupil midwives, by their regulations, must conduct the case entirely and record the patient's name. Resident assistants, rather than house-surgeons, should do the teaching in the labour wards. The medical student as a rule does not acquire anything like the same experience in clinical midwifery as the pupil midwives—I am speaking of the London area more especially. A practitioner must have the knowledge and experience of normal cases in order to cope efficiently with complications. It is well to teach students that most patients will do better if carefully guided into natural ways, and that intervention is the resort of the inexperienced.

Midwives.

It is hoped that the position of the midwife will be more clearly defined and that the present unsatisfactory rate of remuneration will be improved. The service of midwives must be subsidiary to that of the medical profession, not a rival one. There should be less criticism and much more co-operation between doctors and midwives. This I feel confident will be brought about by ante-natal work. If midwives were trained in the rudiments of medicine and surgery they would be of additional value in looking after medical or surgical complications, and their relationship to the practitioner would be more easily defined. Registration with a doctor of an expectant mother would ensure that the midwife has prompt assistance if required at labour. Many midwives undergo great anxiety because medical help is unobtainable; I have known of cases where four or five doctors have been sent for before one could be found or induced to attend. I have always expressed the opinion that midwives should be inspected by senior members of their own profession and not by women doctors. If a doctor is employed, he or she should be allowed to carry out treatment if required, and not merely report on the conditions found.

Finance is the greatest problem of all, both in public health and in private practice. The public must learn that if they want efficiency this has got to be paid for. It is for us to point out the way and let those concerned find the financial support.

We look forward to a new era now that the advice and help of the obstetricians of the country is available as a corporate body—namely, the College of Obstetrics and

Gynaecology. In co-operation with the Boards for the training of midwives, it will prove of value to the public health authorities in the future.

I have touched on many points of a controversial nature, but I only speak from the small area of my own experience.

REFERENCE.

THE PREVENTIVE ASPECT OF OBSTETRICS.*

BY

GILBERT I. STRACHAN, M.D., M.R.C.P., F.R.C.S.,

ASSISTANT GYNAECOLOGIST, CARDIFF ROYAL INFIRMARY; FIRST ASSISTANT TO THE PROFESSOR OF OBSTETRICS AND GYNAECOLOGY, WELSH NATIONAL SCHOOL OF MEDICINE.

THE importance of this branch of preventive medicine needs no stressing at this time of day, when a large and constantly increasing experience has demonstrated, not only to our profession but also to the lay public, the enormous value of preventive methods in obstetrics and the large amount of foetal and maternal life that can be saved by their appropriate application.

Much has been written on this subject, especially from the institutional point of view, but I wish to speak now more particularly of the methods which may be used in carrying out ante-natal investigation in domestic practice, either in the consulting room or in the patients' homes. It will be found, I think, that the matter is much less formidable than might at first sight appear, and that the application of common-sense rules will clear away the greater proportion of difficulties. I would recall that this was the main subject for discussion in the Obstetrical and Gynaecological Section at the Bradford Meeting of the Association in 1924, and the papers then read will well repay perusal.

Ante-natal examination may vary in extent and thoroughness, but what I want to indicate in this paper is the minimum which should be expected of any general practitioner, and which is expected under such a scheme as the National Maternity Service Scheme of the British Medical Association.

When a pregnant woman comes, either of her own free will or on the recommendation of a midwife, to consult her doctor, the first glance will tell him whether she is of a healthy appearance or poorly nourished, of normal stature or undersized, and whether she walks normally or with a limp, so that even now a definite number of important points can be noted.

The next thing is to take her history, and here again a few minutes' conversation will bring out several more important points. The duration of amenorrhoea and the date of the onset of the last menstrual period should be inquired about. It is remarkable how definite the majority of patients are on this point; this is fortunate, as the period of amenorrhoea still constitutes the most exact method we have of estimating the approximate date of confinement. The history of previous pregnancies and labours (if any) is also of great value. If one patient says that in the previous pregnancy the legs and face became very swollen, it would indicate the necessity for a very strict examination of the urine, while if another reports that, of several previous pregnancies, only one child is alive, the others being born dead after prolonged labours with instruments, a careful examination of the relative size of head and pelvis would be indicated. In the primigravida, of course, we have no previous history to guide us, and we have to form our own opinion from the beginning.

Other points to be inquired about are the condition of the bowels. Most women suffer from more or less constipation, and this has to be borne in mind when advising the patient about her habits. It has to be emphasized that if a satisfactory daily motion of the bowels is obtained, the likelihood of toxaemia or eclampsia is remote. The amount of urine passed is best ascertained by asking if she passes about the usual amount, or more or less. The necessity for emptying the bladder during the night is often the first thing that will bring home to a patient the fact that she is passing more urine than normal. Oedema of legs or face, indigestion, sickness, headaches, interference with sight, and the occurrence of any bleeding should also be inquired into. Finally, and especially if she appears to be in the later months of pregnancy, the date when foetal movements were first felt should be inquired into, as this usually indicates mid-term and may, along with the period of amenorrhoea, give further information regarding the present duration of pregnancy. Usually, however, the patient is seldom so exact about this date as about the last menses.

Only after settling these points should we proceed to the physical examination. The first point to be determined now is this: *Is the patient pregnant?* While it can be taken for granted that, in the great majority of cases, when a woman says she is pregnant, she is pregnant, this is not always so. I have known a patient with a fibroid, who had several children, declare, even on the morning of operation; that she distinctly felt foetal movements; while in another case, a lady who was several weeks "post-mature" showed no signs of going into labour, merely a fat abdomen and a uterus ten months post-menopausal being found. Many other instances in both directions could be quoted. It is common knowledge that pregnancy may be very difficult to diagnose, and mistakes are often made in this way, but this is not evident to the lay public.

Certain points may be noted here. First, before the tenth week it is not possible to be certain that the uterus is pregnant, and often time has to be allowed for confirmation or the reverse. Secondly, before the uterus becomes an abdominal tumour it is felt on bimanual palpation as enlarged, of a peculiar doughy consistency, globular shape, and strongly anteverted, so that the cervix may be pushed far posteriorly. If it should be retroverted with the cervix anterior, incarceration must be suspected, and steps taken to lift the uterus clear of the sacral promontory, and if necessary to keep it up for a few weeks with a pessary. Thirdly, when the uterus comes up into the abdomen it forms a swelling whose outlines are characteristically vague, and in this way it is unlike even an ovarian cyst and much more so a fibroid, whose outlines are usually clear-cut.

There are certain points characteristic of the pregnant uterus, and among these may be mentioned the presence of a uterine bruit. This is caused by the distended uterine vessels, and is therefore heard at the sides of the uterus. Theoretically any uterine tumour—for example, a fibroid—may exhibit such a bruit, but in practice it is not usually found apart from the pregnant uterus. While the palpation of foetal parts and of a presenting part indicates a pregnancy and nothing else, the elicitation of foetal movements and of foetal heart sounds demonstrates not only pregnancy but a live pregnancy. These are all, therefore, positive signs, but one or more, seldom all, may be absent even in normal pregnancy.

The next point to determine is whether the patient is pregnant according to the duration of amenorrhoea. Often a patient with, let us say, three months' amenorrhoea, will show the uterus enlarged to the umbilicus—that is, to five months—and while in the majority of such cases the discrepancy is due to an error in the patient's dates, or possibly to some menstruation occurring in the first month or so of pregnancy, still the possibility of such a condition as hydatidiform mole or an associated pelvic tumour must be borne in mind. On the other hand, the uterus may be much smaller than for the duration of amenorrhoea, and may not increase in size even after waiting and several examinations. Such a condition would indicate death of the ovum without expulsion, the carneous or fleshy mole, and steps should be taken to evacuate the uterus.

But if all is normal here the pelvic measurements should be taken *and should be noted*. The interspinous, intercrestal, external, and diagonal conjugates can be taken with an ordinary pelvimeter in a very short time, and from the two last the true conjugate can be estimated. It is very useful to take also the transverse at the outlet,

* A paper read before the South-West Wales Division of the British Medical Association at Carmarthen, December 13th, 1929.

between the two ischial tuberosities and in a line just in front of the anal orifice. Blair Bell points out that in certain cases unsuspected contraction of this diameter will cause the head to be pushed posteriorly, with a severe perineal laceration.

Vaginal discharge should be looked for and its significance gauged. In the multipara it is usually due to a chronically infected cervix lacerated at a previous labour, but in a primipara, and especially if associated with inflammatory urethral and vulval signs, it is more likely to be gonorrhoeal. In the latter case special advice should be sought and the child's eyes treated with silver nitrate at labour. The danger to the mother is mainly puerperal and inflammatory, and frequent cleansing during pregnancy with a douche and absence of manipulation at labour are called for.

The tongue and teeth should be examined and the conjunctivae inspected for any anaemia, and finally a specimen of urine should be tested. This may be drawn off by catheter, but it usually suffices if the patient brings a specimen in a bottle, and this can be tested at leisure.

Now many and elaborate tests may be carried out on the urine, but much may be learned from the usual tests; it is advisable, however, to concentrate on two main points. The presence of albumin is obviously the most important of these, and it must be remembered that it is the presence more than the amount of albumin that matters. It must also be borne in mind that although eclampsia may follow albuminuria, the most common grave sequel is chronic nephritis, with all its later dangers, as has lately been shown by Young and Gibberd. If no albumin be present the next important point to determine is the specific gravity of the urine. A persistently low specific gravity below 1010 may be an even earlier sign than albuminuria of breakdown of renal function.

It is hardly necessary to recapitulate the valuable information that has been gained by this examination. The patient is pregnant to a certain duration, the pelvis is full-sized, she is in general good health, there is no oedema or other toxic sign, and the urine is normal. Or the reverse of one or more of these points may be present.

The next thing is to advise the patient about her habits in pregnancy. This advice will often be disregarded, but it should always be given. It is important to give a few points of clear guidance which she will remember rather than much advice which will be blurred in memory and soon forgotten.

The first and most important is to guard against constipation; seldom will toxaemia develop if the bowels are acting daily. While purges may be necessary, the best usual means of overcoming constipation is by taking daily exercise, but not excessively or to the point of exhaustion, and by increasing the intake of fluids; a glass of warm water first thing in the morning and last thing at night is most beneficial, not only in this way but also in stimulating renal action. Green vegetables and fresh fruit may also be advised, but these are often relatively expensive. An occasional dose of magnesium sulphate is advisable, even if the bowels are reported as acting normally.

Regarding diet, the best thing is to tell the patient what she must not take. Red meat, because of the high protein content, should be taken sparingly and in the later months of pregnancy especially so, until the patient is allowed meat not more often than three times weekly. Pastry, highly spiced food, and fried dishes should also be forbidden, and, in general, boiled or stewed food is better than fried. The value of oatmeal as a cheap, nourishing, easily digested and bowel stimulating diet must not be forgotten.

Another appointment should now be made, the date depending on circumstances, but it should be impressed on the patient that if swelling of legs, scantiness of urine, indigestion, jaundice, headache, or disturbances of vision should occur at any time before that date she must come to see you or send for you at once.

When should the next visit be? This will, naturally, depend on circumstances, and it may be that several visits may be necessary. From a purely theoretical point of view it may be argued that even in a case progressing normally in pregnancy such visits and physical and urine examinations should be frequent, in order that any mechanical or urinary abnormality may be detected in its earliest stage; while it may quite properly be laid down that in the second half of pregnancy the patient and the urine should be examined every month. In any event, if conditions are found which cause uncertainty or concern in the mind of the medical attendant, such as doubt of pregnancy or doubt regarding presentation, he should fix another examination after a time sufficient for these doubtful points to have resolved themselves, and in most cases an interval of one month will suffice for this. If grounds for doubt on any point still remain, consultation with an obstetrical specialist should be recommended.

Now on the one hand most pregnant women will want to be handled and examined as seldom as possible, while; on the other hand, from the practitioner's point of view, it is important that such examinations should take place at a time or times when the maximum of information can be obtained. It is safe to say, however, that every pregnant woman should be examined at least twice in pregnancy. At about the third month the general appearance, pelvic measurements, estimated date of labour, and the other points previously indicated can be ascertained; but a number of other points cannot as yet be determined, and a second and final examination to determine these should be carried out about four weeks before the estimated date of labour—that is, at the end of the thirty-sixth week. Most important final points can now be ascertained.

The condition of the bowel should again be carefully inquired into; also the general health, oedema, and the presence and duration of foetal movements. A glance at the abdomen may convey an almost subconscious impression that the uterine enlargement is not as high as might be expected, and that the abdomen is unduly bulging in the flanks. Such a state of affairs may indicate a transverse lie. In another case undue distension may lead one to suspect twin pregnancy or hydramnios. Generally the fundus, however, is felt at this stage up near the ensiform cartilage, with the long axis of the uterus in the line of the patient's trunk, and this part should be carefully palpated. If the consistency of the fundus is like that of the rest of the uterus it can be taken that the fundus is occupied by the breech of the foetus, and that it is a head first presentation, but if the hard and globular foetal head be felt here it is, of course, a breech presentation.

The uterus should now be carefully palpated on each side to determine on which side is the foetal back and on which are the limbs, and great difficulty may be found here. In many cases few or no foetal limbs can be palpated with certainty on either side, and this is a good sign, as it indicates the great improbability of an occipito-posterior lie. In other cases the limbs can be palpated with ease, it may be with suspicious ease, and such a condition should always make us suspect this complication.

In examining next the lower uterus our main object is to find out what is the presenting part, and, secondly, does that presenting part fit into the pelvic brim? Palpation on each side may show the bony skull, which cannot be completely followed down as it is entering the pelvis; or it may not yet be in the pelvis, and the two hands may be brought together above the symphysis and below the presenting part. Again, in a breech the presenting part will not be hard and globular, but of a softer consistency.

Before making a vaginal examination it is well to listen for the foetal heart, and the best place to begin is near the umbilicus. From here it may be followed in a radiating direction and the position of greatest intensity, above or below and to right or left, determined. If the foetal heart cannot be satisfactorily auscultated here it should be listened for in either flank. If heard distinctly in the flank and not in front, and if foetal limbs have been easily palpated, the suspicion of an occipito-posterior lie becomes almost a certainty.

A careful vaginal examination should now be carried out. The round globular vertex may be found here, and, if so, its size relative to the pelvic brim can be easily determined by Munro Kerr's manipulation. In carrying out this test the thumb of the pelvic hand is placed on the front of the symphysis, while the index

and middle fingers in the vagina touch the presenting head. With the other hand the head should be strongly pressed down into the pelvis. If the head fits the pelvis it will be felt to descend on to the vaginal fingers, while if there is just a little tight fit there will be no descent. If the pelvis should, however, be definitely contracted or the head enlarged, as in hydrocephalus, it will not only fail to descend, but on pressure from above will impinge on the thumb placed on the pubis, thus indicating the presence of definite overlapping. Sometimes, however, it will be difficult or even impossible to feel the presenting part at all, and in such a case, and especially in conjunction with abdominal findings, the suspicion of a malpresentation is greatly strengthened. Finally, in the case in which a head appeared to be palpated at the fundus, a head may also be palpated below. There are two possible explanations here: the first impression may have been a mistaken one, and it may be a normal vertex, or, again, it may be a case of twins. This may be the only sign of twin pregnancy, as in a large proportion of these cases no undue abdominal distension is to be found. In such a case it may be that two foetal hearts beating at different speeds can be auscultated, and this should always be sought for. In doubt in a case of this kind, or in other cases such as suspected breech or suspected extended legs, an *x*-ray plate should be ordered. *X* rays constitute an everyday and valuable adjunct to the other forms of physical diagnosis, but it must be used as an adjunct and never as a quick means of seeing that all is well without the trouble of detailed physical examination.

Finally, a complete urinary examination must never be omitted at this stage. If all is normal, good and well, but definite albuminuria may be present without any obvious symptoms, and may lead to an acute disaster such as eclampsia or to the even more formidable chronic nephritis.

I have said enough, I think, to indicate the large number of obstetrical abnormalities which can and should be discovered by ante-natal examination at a time when appropriate and deliberate steps can be taken for their rectification. The nature of the steps is, in many cases, obvious.

While many points and possibilities have been discussed, the examinations I have detailed can be carried out by any general practitioner in a few minutes, and if all is found normal his mind can be at rest with the practically certain knowledge that the labour will be normal, and this is surely worth having.

There are few branches of medicine in which preventive methods can be practised to such good effect as in obstetrics, and it is in this direction that the art is progressing and will continue to progress. How much foetal death can be prevented by the rectification of a breech, especially in a primipara? How much maternal death or morbidity from shock or sepsis can be prevented by the early recognition of a contracted pelvis? How much eclampsia and nephritis can be prevented by the early recognition of albuminuria, the first danger signal of toxaemia? These and other calamities can and should be prevented, and it is in this direction that the State and the public will expect more efficient service from us in the future.

But when labour comes on, in spite of the most careful supervision, unforeseen complications may occur. Rarely, for instance, is a face presentation diagnosed before labour, and often the necessary extension of the head occurs only with the onset of uterine contractions. Again, the gush of liquor amnii at rupture of the membranes may wash down a loop of the cord. Or a case which, by all criteria seemed occipito-anterior is found at labour to be occipito-posterior.

These points are mentioned merely to emphasize the fact that extended use of preventive ante-natal methods must never allow our manual dexterity at the actual labour to lack efficiency. Attendance at confinement and the relief which we can give at that time is the sheet anchor of the faith which the pregnant woman has in us, and while our skill in emergency obstetrics of this sort should be supplemented by the acquiring of ante-natal skill, it is to be hoped that the time will never come to the general practitioner when his hand has lost its cunning.

ANTE-NATAL, NATAL, AND POST-NATAL PROBLEMS.*

BY

W. H. F. OXLEY, M.R.C.S., L.R.C.P.,

MEMBER OF THE BRITISH COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS.

AFTER working for many years at prophylaxis applied to midwifery, I feel convinced that no great progress will be made in this comparatively newly developed art until it is recognized by the profession and impressed upon our governing bodies that the co-operation of all concerned—doctor, midwife, and patient—is necessary. And in our profession itself all branches have their special part to play: the General Medical Council, to see that the student is properly educated; the obstetric specialist, to do the teaching and to help the general practitioner in difficult cases; the members of the public health service, to educate the mother in mothercraft and in the need for taking advantage of the facilities provided for her; and, lastly, the general practitioner, whose duty it is to be ready at all hours of the day and night to help the midwife and to guide back to the physiological path all mothers who show the slightest tendency to deviate therefrom.

The official maternal death rate has been stationary for many years, and many causes which are beyond the control of the profession are responsible for this—social, such as the reduction in the size of families since the war, and the consequent higher proportion of first labours with their added risk; administrative, such as differences in classification adopted by the Registrar-General from time to time. I have no doubt that such factors mask a fall which has in fact taken place. There is no doubt, however, that avoidable clinical factors are also at work, and I hope to indicate some ways in which improvement in these may be brought about.

The medical student has had in the past, and still has, insufficient practical experience, however good the theoretical teaching may be; and therefore, when he comes into private practice, and is forced by economic pressure to do midwifery under adverse conditions, he is unable to use his knowledge to the best advantage. Nay, more: I would say that the importunities of the patient and of her relations and the handy-woman, the doctor's tiredness of the case through having had many unnecessary calls, his expectation of a busy time next morning, and the many other trials which we all know well, would lead any man who had not an iron will to get the case over, even if doing so should imply a certain lapse from the strictest professional rectitude. I feel convinced that this is the true reason for the many cases of "failed forceps" which are reported in the journals. If that is so, we must see that the teaching is of such a kind as to imbue the student with what may be called an obstetric conscience, and that he will, when qualified, be able to take his part in a national midwifery service, his special duties in which will be defined and the means provided for carrying them out efficiently.

I am lucky in that I have had the advantage of working for many years under such a system as is envisaged in the British Medical Association's national scheme, and I think it may be useful to indicate briefly what this has been able to accomplish.

The East End Maternity Hospital was founded in a small way in 1884, and since then has increased until we now have 56 beds and attend 2,000 cases yearly, about half of which are in patients and the other half attended in their own homes. There is no resident doctor. The hospital is under the direct management of the lady superintendent, who is a midwife, and the routine work is done by midwives. Doctors selected from among the general practitioners of the neighbourhood form the medical staff, the senior member of which pays daily visits, conducts a clinic for abnormal ante-natal cases, and he or one of the junior men is called by the midwives for abnormalities.

The cases are unselected, no patient is refused except on the ground that she is able to pay for her own doctor, and no patient is sent elsewhere on account of obstetric abnormality. That is to say, it is worked on pretty much the same basis as the service recommended by the British Medical Association and by the Midwives Committee of the Ministry of Health.

* A British Medical Association Lecture delivered to the Gateshead Division of the Association on December 15th, 1929.

Table showing Deaths in the East End Maternity Hospital throughout its History.

Period.	No. of Confinements.	No. of Deaths.	Rate per 1,000.
IN-PATIENTS:			
1884–89	427	1	2.34
1890–97	1,629	12	7.37
1898–02	1,278	2	1.57
1903–07	1,966	6	3.05
1908–13	3,223	10	2.13
1914–20	4,970	7	2.01
1921–26	6,373	3	1.10
1927–28	2,517	47	1.19
	22,383		2.10
OUT-PATIENTS:			
1830–97	1,548	3	1.94
1898–02	1,530	5	3.27
1903–07	2,384	1	0.42
1908–13	5,597	1	0.18
1914–20	7,490	8	1.07
1921–26	7,027	2	0.29
1927–28	1,608	—	—
	27,184	20	0.74

This gives a death rate of 2.1 in the hospital and 0.74 on the district. On district and in hospital combined the rate is 1.35 for the whole period.

Now if such a system is to come into being over the whole of England and Wales, and to get good results, it follows that every doctor undertaking the work must know how to apply the principles of prophylactic midwifery in all cases, and must have at his finger-ends the technique necessary to deal to the best advantage with those in which prophylaxis has failed. This means technique of a very high order, because, although the number of maternal deaths taken as a whole is large, yet the number of dangerous cases which fall to the lot of any one doctor in the course of a year is few or even none at all, and yet he has to be at concert pitch all the time.

Sufficient stress has not been laid in the past on the prophylactic side of midwifery, with the result that all except the recently trained men have had to learn it for themselves, and perhaps some of them do not even now realize its value. Prophylactic midwifery does not apply only to ante-natal work; it continues throughout labour and the puerperium, and even further, for we know that mistakes made in one confinement may have effects reaching to future pregnancies, and even through the whole of a woman's life. Thus a neglected albuminuria in one pregnancy may lead to concealed accidental haemorrhage and death of the mother in the next, and many instances of the same kind could be cited. We must therefore look upon the process of reproduction as one whole, the problems of each stage overlapping one another. In the title proposed to me for this paper the division into three parts—ante-natal, natal, and post-natal—is made for descriptive purposes only.

The next table shows the advantage of ante-natal work in lowering the maternal death rate. Although this had been done to some extent from the foundation of the hospital, it was not until after the war that the full benefits of such work were realized, and steps taken to so organize the department that every patient had necessarily to be examined.

Period.	Cases.	Deaths.	Rate.
1884–1913	19,584	37	1.9
1921–1928	17,525	12	0.68

The institution of full ante-natal work with compulsory attendance has been followed by a drop in the already low mortality to a third of its former level.

There is no mystery in ante-natal work. The idea that the average general practitioner is unable to look after the health of a pregnant woman, to search for septic foci, to examine her urine, to gauge the size of the pelvis, and to find out whether the child is lying correctly, is not in accordance with facts. If he is given the incentive to do it, and the advantage of a few demonstrations at a good clinic to see what should be done, the rest depends upon himself. He will make mistakes, especially as to the relative size of head and pelvis, as we all do, but his skill will increase with experience, and this experience will be impressed upon him by the many unnecessary night calls he will get if he shows any tendency not to profit by it.

For this reason it is of the utmost importance that the person who does the ante-natal work should be responsible for the confinement.

It is not only the doctor who has to keep up to the mark—there is the patient, her negligence, and the prejudice of her friends. Patients in the past have been lost to the doctor through insistence on ante-natal care, but now those days are going, and anyone who neglects it will be rightly blamed should untoward results follow. The doctor ought to be well paid for ante-natal work, and the financial provisions should be so arranged that success in preventive midwifery should not reduce his income.

Ante-natal care is the foundation of good midwifery; it can eliminate eclampsia, and has an important indirect effect upon the two other principal causes of maternal deaths; but it is the foundation only, and no amount of ante-natal care can do away with the necessity for really good midwifery throughout labour and the puerperium. One feels that the authorities, acting on the analogy of the child welfare centres, which have done so much to save infant life, have not quite realized that ante-natal work is simply the preparation for an emergency; the labour, and that its full benefit cannot be obtained without complete co-operation with the man who is bound to look after the patient in her emergency. This want of co-operation has been so marked in some quarters that there appears to have been an attempt to side-track the general practitioner altogether. Now, however, that idea has gone, for in the Memorandum on Ante-natal Clinics, recently issued by the Departmental Committee on Maternal Mortality, and in the report published this year by the Ministry of Health on infantile mortality, definite recognition is made of the possibility (it is only a possibility at present) that the general practitioner may have to take over a large part of the examinations now being done by the ante-natal clinics, leaving to them the work which they can most usefully do, such as the teaching of mothercraft, the following up of cases, and work of that nature. The reason for this is clear: that the general practitioner must, from the very nature of things, be the man upon whom the nation must depend at the crucial time, and anything which tends to diminish his skill or his interest in midwifery, however good it may be in itself, is bound in the long run to raise maternal mortality. Unless the general practitioner is to be cut out of midwifery altogether, which is impossible, any new service that is devised must depend for its success upon increasing his skill and interest.

Although forced to cast strictures upon part of the present working of ante-natal clinics as often conducted, nothing but praise can be given to the consultative and educative clinic. The aims of this are well known in the North of England through the work now being carried on by Dr. Farquhar Murray and his colleagues. Such a clinic will play a most important part in the midwifery service of the future, one of its chief duties being the helping of general practitioners to become efficient in this branch of the work. I am also pleased to see that the somewhat thinly veiled antagonism between general practitioner and medical officer of health has now, in most areas, been broken down, and that the two are now anxiously awaiting a lead as to how the necessary co-operation can best be obtained in practice.

Let us now consider what part the general practitioner can play under this new midwife-doctor-hospital system in diminishing the three chief causes of maternal mortality—eclampsia, haemorrhage, and sepsis.

Elimination of Eclampsia.

I use the word elimination advisedly, for, under the treatment we employ at the East End Maternity Hospital, out of the last ten thousand consecutive confinements we have had only one slight case. This occurred in a patient who had escaped the ante-natal net for three weeks. She had one fit after delivery and an uneventful recovery.

The first link in the chain is the regular examination of the urine by the midwife at least every fortnight, and the reference to the doctor at once of all cases of albuminuria, however slight. At present she does not always do so, arguing to herself that slight albuminuria means

a slight illness. It must be clearly laid down that what concerns her is simply the fact that albumin is present. The case is abnormal and one for the doctor. The next link is the admission of the patient to hospital. Home treatment, especially among the working classes, is extremely unsatisfactory. All cases should be admitted at once, with the possible exception of women at term who show no physical signs or symptoms and have no rise of blood pressure (albuminuria of labour).

In hospital energetic eliminative treatment must be carried out—hot baths, packs, castor oil, Epsom salts, enemata, and starvation. Nothing is so impressive as the effect of this treatment. A patient waterlogged, passing only one or two ounces of urine, solid with albumin, and with a blood pressure of 180 mm. or more, in most cases presents an entirely different picture in twenty-four hours and is on the high road to recovery. In a private house, surrounded by her friends, the patient will not stand the treatment.

A few cases do not clear up altogether: the symptoms disappear, the blood pressure goes down to normal, but a cloud of albumin remains. The danger of eclampsia has gone, but now comes the question how long this condition can continue without causing permanent damage to the kidneys—either a definite chronic nephritis or such slight impairment as to show itself only as a recurrent toxaemia when the kidney has to undergo the increased strain of another pregnancy. A complete answer cannot be given at present, but a rough guide which has been adopted at the East End Maternity Hospital is to induce labour at the end of a fortnight. There is a temptation to wait a little longer for the sake of the child, but it is a mistake to do so. If induction is delayed it will nearly always mean a stillborn child or permanent injury to the kidneys. In a pre-eclamptic patient induction is indicated if improvement does not take place in twenty-four hours. Albuminuria occurs frequently in multiparae, but as it does not give rise to pronounced signs it is apt to be overlooked. Energetic treatment of the first toxaemia diminishes its recurrence.

Whether or not it will be found practicable in the new service for general practitioners to continue in charge of their patients in hospital, I am sure it is an end to be aimed at, for these patients do dislike removal, and this dislike would be much diminished if their own doctor were to continue attendance. Eclampsia is nearly always due to neglect on the part of the patient, and if things are not made easy for them there will be no chance of eliminating it.

Ante-partum Haemorrhage.

Although we cannot at present do much in the prevention of ante-partum haemorrhage, we can do a little. Efficient treatment of toxaemia does reduce the number of those horrible cases of concealed accidental haemorrhage connected with albuminuria in which the uterus is so riddled with haemorrhages that if the mother is delivered alive she dies from post-partum haemorrhage owing to the inability of the damaged uterus to contract.

The greatest attention should be paid to all slight haemorrhages in the last two months of pregnancy. All such cases should be removed to hospital and treated by rest in bed. If left at home they may get a severe haemorrhage at an awkward time. The same principle applies when the bleeding is severe; a case loses half its terrors when once admitted to a well-equipped labour ward. Many patients, however, are not seen until they are too ill to be removed, and must be treated at home. If the bleeding is still going on it must be stopped—that is an essential; but in many cases the doctor will find on arrival that the patient is collapsed and pulseless, and that there is no actual bleeding at the moment. Here I should like to put in a warning about the danger of intrauterine manipulations in a collapsed patient. Judgement must be used in each individual case, for if version is done at once in such a patient, especially if the os admits only two fingers, the shock and the fresh bleeding, which goes on all the time the foot is being coaxed through the os, are sufficient to turn the scale against the patient. The right thing to do in such cases is to treat the collapse with blankets, hot-water bottles, and saline injections. The doctor should remain with the patient. Unless the bleeding recurs intrauterine treatment should be put off until she has recovered from her collapse. A restless patient should be given morphine, because if she exposes herself to cold by kicking off the bedclothes she will die.

The value of saline injections under the breasts for all cases of haemorrhage can hardly be overestimated; they are so simple to give, and the apparatus, consisting of a rubber douche bag and a couple of needles, should be carried in every midwifery bag. The filling of the subcutaneous tissues with two to four pints of saline should in most cases be started before the intrauterine work is begun. The fluid acts as a reservoir upon which the tissues can draw at need. Blood transfusion is not of much value in private practice. The technique is complicated, a donor is not always handy, and the apparatus is likely to be out of order when wanted.

For stopping the bleeding in placenta praevia turning is still the most useful form of treatment; it gives one such a sense of security, and rightly so, for a pull on the leg will always control any further bleeding. Champetier de Ribes's bag often leaks when wanted, and is difficult to sterilize in emergency. Willet's forceps are of value in cases where the os is not sufficiently open to allow of turning, but are somewhat difficult to apply in just those cases. Some cases in multiparae, or where the labour is premature, are best treated with pituitrin. For emergencies any method which requires fingers and not instruments always has the advantage.

After turning it is tempting to hurry proceedings, but that may be fatal. The uterus should be allowed to empty itself, even if it takes some hours, and no attempt at extraction should be made, with the exception of a 2 lb. weight attached to the leg to keep it *in situ*. The doctor must be within call all this time, as his presence is absolutely necessary when the baby is delivered in order to check the slightest tendency to further haemorrhage. I have never seen a mother die from her first haemorrhage, but even half a pint coming after delivery may prove fatal in an already exsanguinated mother.

No case has occurred within the history of the hospital which could not be successfully treated by one of these methods. The foetal death rate is high, but if we thought more of the foetus I doubt whether we should show an unbroken series of maternal recoveries.

We have lately been adopting a procedure for central placenta which has been successful in saving the life of the foetus.

If the patient is first seen with an os too small to allow of turning, the placenta is separated around the lower uterine segment with the finger. This causes smart haemorrhage, which soon stops with rest in bed and morphine. In the course of a day or two the os will be found sufficiently dilated to allow of turning. When doing this the placenta is held down with tissue forceps, and another pair is used to make carefully a hole in it for the finger. As no further separation of placenta takes place there is no bleeding during this operation, and sufficient placenta remains attached to allow of the foetal respiration.

In accidental haemorrhage the bleeding is stopped in nine cases out of ten by rupturing the membranes and applying a tight binder, again using saline injections to replace the fluid which has been lost. In only a very few cases is it necessary to plug the vagina.

The next table gives the cases of ante-partum haemorrhage which occurred during the last four years and were

Cases of Ante-partum Haemorrhage treated during the Years 1925–28.

	1925.	1926.	1927.	1928.	Total.
Placenta praevia:					
Number of cases	9	11	14	6	43
Maternal deaths	0	0	0	0	0
Foetal deaths	2	10	10	0	22
Accidental haemorrhage:					
Number of cases	15	14	10	15	54
Maternal deaths	0	1	0	0	1
Foetal deaths	5	7	5	4	21

treated on the principles I have just described. The one maternal death was an unbooked case of concealed accidental haemorrhage. On the arrival of the midwife the patient was collapsed; she was delivered alive, but died of post-partum haemorrhage.

Avoidance of Sepsis.

No doubt the only certain method of avoiding sepsis is to follow the full surgical procedure of guarding against the admission of germs by all possible routes. This includes the bathing of the patient, the sterilization of cervix and vagina by some such preparation as brilliant green, the wearing of sterile stockings to the thigh, the shaving of the vulva, the wearing of sterile gown, gloves, and mask, with the possible exclusion from the labour room of any person found on bacteriological examination to be harbouring haemolytic streptococci. The patient should then be restrained from movement lest she touch any unsterile article, and the whole process have to be gone over again. This sterile life should last from the first labour pain until the raw placental site has become covered with fresh mucous membrane. The above procedure is simply bringing things to a logical conclusion, or (considering the number of emergencies which occur in midwifery) perhaps I should say "illogical." We may have to do it all, but before we go so far I venture to think that we may do many things to obviate its necessity.

In the first place, it seems to me that the predisposing causes are not sufficiently foreseen and guarded against. With us nearly every case of septic absorption occurs after a difficult or prolonged labour, perhaps terminated by manual rotation or forceps, and with an unsatisfactory third stage due to uterine exhaustion. In other words, the problem is largely one of ante-natal care combined with careful midwifery during labour. Avoid trauma and exhaustion, and see that the uterus is empty, and cases of morbidity will be few. Low forceps carefully used is not followed by more morbidity than is normal labour.

The next table shows clearly the relation of abnormal labour to sepsis. Sepsis is here taken to be any rise of temperature to 100.4° for twenty-four hours which cannot be accounted for by physical signs elsewhere than in the genital organs. It will be seen that it is over twenty times as frequent after abnormal as after normal labour. Incidentally, this table shows the greater incidence of sepsis in primiparae—nearly three times as much. I think this is probably due to the trauma inevitable in a first labour.

Incidence of Sepsis.

	Hospital.		District.		Total.	
	Cases.	Sepsis.	Cases.	Sepsis.	Cases.	Sepsis.
Cases following normal labour.						
Primiparae	1,769	8	294	0	2,063	8
Multiparae	2,672	3	3,275	4	5,917	7
Total	4,441	11	3,569	4	8,010	15
Cases following abnormal labour.						
Primiparae	212	11	20	0	232	11
Multiparae	170	7	74	2	244	9
Total	382	18	91	2	476	20

The incidence of abnormal labour is ... ... 5.6 per cent.
The incidence of sepsis following normal labour is ... 0.19 "
Multiparae 0.13 per cent.; primiparae 0.38 per cent.
The incidence of sepsis following abnormal labour is... 4.2 "

Secondly, there is a wealth of evidence showing that the risk of contagion to normal cases in hospital is one that cannot be ignored. This risk is especially great in those hospitals which take in infected or potentially infected cases, but it is by no means absent in others. It must always be considered before advising admission in abnormal cases whether the benefit derived from the increased facilities for doing good work in hospital outweighs this added risk. It seems as though until we have discovered some certain routine to avoid infection, the normal case is more safely treated at home.

The third point concerns sterilization of the hands. The wearing of gloves in domiciliary midwifery is not quite comparable with their use in surgical operations. The doctor has necessarily during the course of labour to touch many things which are not sterile, and therefore the most important thing, whether gloves are worn or not, would seem to be to recognize the necessity of frequent rewashing and dipping of the hands in an effective solution such as mercury perchloride 1 in 1,000.

Here let me refer to the importance of thorough investigation of the state of the vaginal mucous membrane after every forceps case. We all know that the application of forceps is often accompanied by the appearance of a trickle of bright red blood from the vagina, but do we all realize that this means a tear of the upper part of the vagina which may need repair? These vaginal wounds are less frequent if really thorough lubrication is carried out. I often think there was a good deal of reason for the practice of old obstetricians who stuffed the vagina with butter before introducing the hand.

When the temperature rises it is important to regard it as due to sepsis until the contrary is established. I often try to hoax myself that it is due to loaded bowel or some other cause, only to be proved wrong later on. I am a great believer in thorough examination of the patient in the lithotomy position in every such case. I know that many obstetricians do not agree with me, but I have not found that there is any risk in careful washing out of the uterus with iodine and in digital exploration and removal of retained products. Such treatment, in cases where there is doubt, will time after time result in the removal of decomposing debris or in the letting free of lochia, retained in the uterus owing to anteversion or retroversion. Raised temperatures due to retained lochia occasionally occur fairly late in the puerperium—say from the eighth to the twelfth day—and are very puzzling; the midwife correctly says that the uterus is not felt, and yet several ounces of offensive discharge may be let out on straightening the cervical canal. If the finger at this stage can be insinuated into the cervix without stretching there is something there which should be removed.

That is a brief outline of our procedure, and it seems to show that prevention of trauma and exhaustion, and the obtaining of an empty uterus, together with careful washing and the use of plenty of mercury perchloride, are of more importance than the full surgical ritual.

As I was one of the first to start a post-natal clinic, it will not be misunderstood when I say that, given good midwifery all through, there is no need to make a vaginal examination in normal cases. In fact, I think the chief value of the post-natal consultation advised in the British Medical Association scheme is that it will act as a check on the work of the midwife. To this end the perineum of every primipara should be inspected, the general and special health of the mother should be inquired into, and if this interrogation discloses possible subinvolution, retroversion, injury to urethra or vagina, or other abnormality, further examination should be made and the appropriate treatment given. If the examination is made too searching it will defeat its own ends because the women will cease to attend. In fact, for both ante-natal and post-natal examination a thorough following-up scheme will be necessary.

I have tried in this lecture to show that the problem before us is by no means insoluble. If you agree that the stationary position of maternal mortality is due not wholly to want of progress in midwifery but to social causes, if I have made it clear that the deaths from the three great causes can be very largely reduced under the general practitioner-midwife-hospital combination, my lecture will not have been given in vain. Much has to be learned by research, but I see no reason for holding a "non possumus" attitude, and firmly believe that, even in the present state of our knowledge, well-considered administrative action will result in a drop in the true maternal mortality rate of over 50 per cent.

THE USE OF PARALDEHYDE BEFORE ANAESTHESIA.

BY

HUGH R. PHILLIPS, M.D.,

ANAESTHETIST, ST. JOHN AND ST. ELIZABETH, ST. VINCENT'S ORTHOPAEDIC, FREEMASONS', AND ITALIAN HOSPITALS.

AFTER using paraldehyde before operations in over 250 cases of all kinds I have come to the conclusion that, so far as my experience goes, its uses are somewhat limited.

Dr. Harold Sington, in the able paper he read before the Anaesthetics Section of the Royal Society of Medicine in the early part of last year, showed the great value of this drug when dealing with children. With most of his deductions I entirely agree, but even in their case the results are not always absolutely satisfactory.

At St. Vincent's Orthopaedic Hospital I have for nearly two years used paraldehyde in every case for operation, and the sister in charge of the surgical division reports that after being put back to bed the patients are usually very sick and often excitable for half an hour, but when that period is over they go to sleep and remain quiet for twelve to eighteen hours. Gas and oxygen, with occasionally a small quantity of ether, is the anaesthetic given. She also states that there is considerable difficulty in getting small children to retain the whole dose, and in such cases apparently the small dose tends to make them excited. At the Hospital for Sick Children, Great Ormond Street, the results are quite satisfactory, and there has been very little vomiting, as also in other nursing homes and hospitals where it has been used by me for children. With them I do not care to use it for abdominal work or with those children who are suffering from shock or much sepsis.

In my series of cases administration of paraldehyde to adults has not been so satisfactory, even with a preliminary dose of omnopon (or morphine), atropine, and scopolamine, as advocated by Rowbotham. To many patients the mere introduction into the rectum is distasteful; many others cannot stand the smell.

As to whether it is going to be a success, a great deal depends upon the nurse who gives the injection; she must be tactful and very patient, because it is most important that the solution should be run in very slowly, as, if it is not, some of the fluid may be returned, in which case the full dose has not been absorbed, with the result that there may be much excitement, occasionally verging on delirium. This possibly necessitates manual restraint for some hours, and at all events very careful watching. Abdominal pain, sometimes acute and which lasts until it is deadened by the action of the drug, is another result of too rapid injection.

In order that full benefit be obtained the administration of paraldehyde should be commenced one and a half hours before operating. It must be given very slowly, and then the patient moved about as little as possible; therefore it is best to place the patient on a trolly either before or soon after the introduction. It is still better to give the solution on the operating table if the patient does not mind the surroundings.

Induction by general anaesthetics is certainly smoother, and a smaller quantity is required; special care must be taken to be sure that the airway is free. It is not, however, easy to be certain when anaesthesia is sufficiently advanced to allow the surgeon to commence his work. Complete relaxation is more difficult to obtain for abdominal work, as one is apt to be misled by the quiet and rather shallow breathing. In brain surgery and profoundly toxic subjects paraldehyde is contraindicated.

The after-effects in adults vary considerably, but I am convinced that among patients who have paraldehyde there is a higher percentage who vomit than among those who do not have it. The vomiting, while it lasts, is severe, but as a rule does not continue for very long. A feeling of general misery for some days is not an uncommon phenomenon after the use of the drug, and one occasionally finds patients who are actually mentally unbalanced for the time being. The excitement or delirium already mentioned places a considerable strain on the resources of the nursing staff, as such cases frequently necessitate two nurses to restrain them.

After the patient returns to bed just as much care must be exercised in preserving the airway free as during the operation, so that until the patient is showing signs of recovering his reflex he must be constantly under supervision.

There are many advantages in the use of paraldehyde, particularly for nervous people and for those who have a strong objection to the smell of ether, or have a dread of losing consciousness. In a satisfactory case the patient knows nothing of going up to the theatre and having an operation, and for many hours time is blotted out. Thyroid cases especially appear to be suitable, and these require a minimum of general anaesthetic.

Tonsillectomy lends itself to a successful exhibition of the drug, because, if the patient is amenable, the first few hours of great pain and discomfort are got over before return to consciousness. Still, even these cases are not without risk, as it is easy to overlook oozing owing to the comatose state of the patient. In orthopaedic work the advantages are similar, except that it may not be wise to use it when the operation is in the region of the hip, pelvis, or upper part of thigh, since some patients, especially young ones, occasionally evacuate some of the fluid.

Undoubtedly certain individuals have an idiosyncrasy towards paraldehyde, and the following two cases exemplify this.

A young healthy man, aged 23, weighing 10 st. 4 lb., was operated on for removal of tonsils; this being one of my early cases, I had ordered 8 drachms in saline to be given an hour beforehand, and soon after an injection of atropine, but no morphine. He arrived in the theatre quite comatose, and did not regain consciousness for forty hours, though the reflexes were active, and during the first thirty hours he could not be roused. His pulse being regular, quiet, and of good volume, I was not worried, but the condition gave rise to much alarm among the nursing staff and also to the patient's relatives.

The second case was that of a boy, aged 9, and weighing 4 st. 5 lb., who was having fasciotomy, wrenching, and plaster done on both feet. He was given 4½ drachms in saline, commencing at 7.30. Atropine was given three-quarters of an hour later, and he was brought up to the theatre at 9 a.m. During induction he was extremely restless and had to be held down. At 4.30 the same evening the youngster was sitting up in bed, very lively, and having a good tea.

I have used paraldehyde in conjunction with spinal injection in a few cases with good results; also together with local infiltration of novocain; men who have used this more than I have speak favourably of this combination.

In conclusion, I consider that paraldehyde should not be given as a routine before every operation, but only in selected cases. Its great advantage is that, when successful, the patient knows nothing from soon after the introduction of the drug until some hours after the operation.

CHOLECYSTO-COLIC FISTULA WITH UNUSUAL RADIOGRAPHIC FINDINGS.

BY

C. J. FULLER, D.M., M.R.C.P.,

PHYSICIAN TO THE ROYAL DEVON AND EXETER HOSPITAL; LATE FIRST ASSISTANT, MEDICAL UNIT, UNIVERSITY COLLEGE HOSPITAL.

THE following case is of interest, both from the unusual radiological findings and from the long clinical history.

The patient, a married woman, aged 63 in 1929, with four children, was admitted to University College Hospital under Dr. Batty Shaw in April, 1923, with a history of a sharp attack of pain in the abdomen lasting about twelve hours and accompanied by vomiting immediately after food. At that time a smooth, oval, hard mass could be felt in the right hypochondrium reaching to just below the level of the umbilicus and measuring 3½ by 3 inches. The lower and median borders of this tumour were smooth and rounded, and the lateral border ill defined. The mass was dull to percussion and was apparently in continuity with the liver. There was no jaundice. A radiogram of an opaque meal showed no abnormality in the alimentary tract, and an occult blood test was negative. She was then regarded as a case of cholecystitis with a Reidel's lobe.

The patient was readmitted in August, 1928, as a surgical emergency, with pains of a severe griping character, irrespective of taking food. These had been present for thirteen days, and were worse for the three days immediately preceding admission. She had vomited once only, immediately after a dose of castor oil taken at home. She was subsequently transferred to my care on the medical side whilst acting as deputy to Dr. Batty Shaw. Between the two attacks the patient had been treated for rheumatoid arthritis, but had complained of no symptoms which might draw attention to her abdomen.

Her condition was as follows: There was no evidence of jaundice. Examination of the abdomen showed considerable divarication of the recti. The liver, spleen, and kidneys could not be palpated, but there was an indefinite mass deep in the right hypochondrium. The tumour noted at the previous admission had disappeared. An occult blood test was positive.

Radiograms of an opaque meal taken at this time showed no abnormality in the stomach, but an unusual shadow was seen passing outwards and to the right from the second part of the duodenum (Fig. 1). The true significance of this abnormality was not realized until an opaque enema several days later was screened and photographed. This was found to pass directly from the colon to the duodenum, while at the same time the biliary passages and even the intrahepatic bile ducts were outlined in an unmistakable manner (Fig. 2).

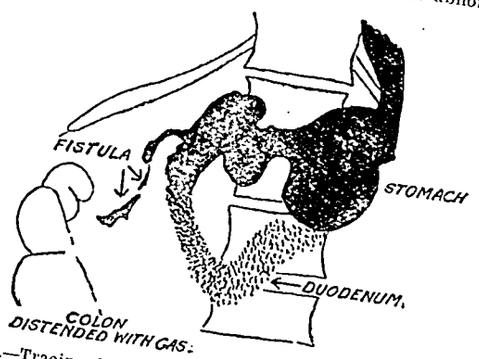

FIG. 1.—Tracing from a radiogram of a barium meal taken in the supine position a quarter of an hour after the meal was given. It shows the stomach partially filled with barium and undergoing active peristalsis. The duodenum is normal, with the exception of a fistulous track passing downwards and to the left from the second part.

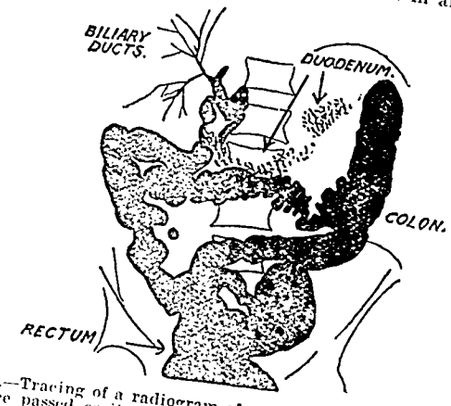

FIG. 2.—Tracing of a radiogram of a barium enema. The opaque substance passed easily into the colon. From a fistulous opening in the transverse colon the barium can be seen to have entered the duodenum and the bile ducts. There was no evidence of barium in the alimentary tract immediately preceding the enema.

A cholecystography was attempted three months later, the dye being given by the oral method. No evidence of gall-stones could be detected, nor was the gall-bladder outlined.

It was decided to adopt an expectant method of treatment, owing to the age of the patient and the absence of any urgent symptoms. This course has, I think, been fully justified, as I have recently (September, 1929) been in communication with the patient, who states that she feels well and has had no abdominal discomfort for some time.

Comment.

The most probable explanation of the case would appear to be that, at the time of her first admission to University College Hospital in April, 1923, she had a mucocele of the gall-bladder due to impaction of a stone in the neck of that viscus. This remained in a quiescent state until August, 1928, her second admission, when the stone ulcerated through the gall-bladder into the alimentary tract. It is well known that an impacted gall-stone may ulcerate either into the colon or the duodenum. In this case, however, it would appear that there is a connexion between all three viscera—namely, the biliary passages, duodenum, and transverse colon. The possible explanations are three:

1. That a single large stone passed into the duodenum and then ulcerated into the colon.
2. That there were two separate stones, one of which ulcerated into the duodenum at the first attack, and the other into the colon at the second.
3. That a stone ulcerated from the biliary passages into the colon, damaging the subjacent duodenum in its passage.

Against the first hypothesis is the fact that a stone sufficiently large to obstruct the duodenum and ulcerate thence into the colon would almost certainly have produced urgent signs and symptoms of acute intestinal obstruction with vomiting. With regard to the second possibility, there was no radiological evidence of ulceration into either the colon or duodenum at the time of the first admission, the occult blood test was negative, and the patient was discharged with what was probably an enlarged gall-bladder. One is left with the third suggestion, which would seem to fulfil all requisites.

Apart from this somewhat academic discussion of the methods by which an undoubted short-circuit has been produced between the biliary apparatus and the large intestine, the really interesting point is that the patient had barium from her colon forced into the intrahepatic bile ducts without any apparent ill effect at the time, and has subsequently remained in good health.

I have decided to call this case one of cholecysto-colic fistula, as although there is no very definite evidence of the gall-bladder in the radiograms, yet, from the absence of obstructive jaundice, the stone could not have been lodged in the common bile duct, but, as has been previously stated, was probably impacted in the neck of the gall-bladder.

I have searched through the *Quarterly Cumulative Index* for references to similar cases. There are several instances reported of barium leaving the duodenum as in Fig. 2, but none, so far as I am aware, in which the intrahepatic bile ducts have been filled.

I wish to thank Dr. Batty Shaw for giving me permission to publish the case.

THE ESTIMATION OF PROTEIN IN URINE AND ITS RELATION TO CASTS.

BY

FRANCIS TEMPLE GREY, M.A.OXON., M.B., CH.M.SYDNEY,

PATHOLOGIST, EAST LONDON HOSPITAL FOR CHILDREN.

IN the routine examination of a large number of nephritics during 1925-26 certain facts came to light which are not without interest to the general practitioner. The first was that the general impression that protein stands in close relation to casts was borne out. In order, however, to arrive at this result it was necessary to have a fair idea as to the amount of protein present and that casts should be properly looked for.

As to casts, I am indebted to Dr. Broughton-Alcock for the following method of search, which I am convinced is the best:

Take up the material to be centrifuged from the bottom of the container, which has been allowed to stand (not too long in the case of children). After centrifuging at a fairly high speed, take up with a bacteriological pipette, which has been thoroughly rinsed between-whiles, about 0.5 c.cm. from the bottom of the centrifuge tube, and spread out in a large flat oblong layer on a slide, the large area thus provided being carefully explored on the mechanical stage with the one-third objective. A good deal of practice is necessary before certainty can be attained, but by this method casts will rarely be missed.

It was evidently of interest to determine the value (if any) of the conventional terms used in estimating protein at a glance, and though it must be admitted at once that those who deal with a large number of specimens are rarely

far out in their estimates, yet, because the general practitioner has not the opportunity to deal with large numbers, and because greater accuracy is desirable, if readily attainable, the following opacity method is proposed:

Add to 5 c.cm. of urine (filtered through two layers of filter paper, and if necessary through sand also[1]) 0.5 c.cm. of 25 per cent. salicyl-sulphonic acid. (It is convenient to have a set of test tubes with the 5 c.cm. level marked.) If the resulting turbidity is outside the range of the standards of the author's proteinometer,* reject that test tube and dilute, say, 1 in 5 with physiological saline, when (after the addition of the precipitant) the resulting turbidity will (unless the amount of protein content be unusually high) be brought within the range of the standards. If the protein content is unusually high, the urine can be diluted to 1 in 10 with physiological saline. The turbidity produced is then compared, by the aid of the green glasses supplied, with the standards, and with practice a good reading is quickly obtained.

With regard to these turbidities, it is to be noted that the turbidity which just obscures print (using a test tube of 5/8 in. bore) corresponds to 0.020 per cent. albumin, or 20 mg. per 100 c.cm.; a turbidity presenting a frosted appearance through which light ceases easily to be transmitted corresponds to 0.070 per cent., or 70 mg. per 100 c.cm.; while at 300 mg. per 100 c.cm. the fluid is so opaque that light is not transmitted at all.

To return to the evaluation of terms in common use in the estimation of protein by the eye, the protein was determined in 401 cases by the method of Roberts and Stolnikow, and averages taken of these values under the heads supplied by the original rough eye estimation—namely, a trace; fair amount; considerable amount; large amount; very large amount. The results are shown in the following table.

Determination of Protein in 401 Cases.

	Cases.	Average Protein.
For a trace	34 gave ...	0.010 per cent.
For fair amount	159 ,, ...	0.050 ,,
For considerable amount ...	101 ,, ...	0.110 ,,
For large amount	60 ,, ...	0.440 ,,
For very large amount ...	56 ,, ...	1.050 ,,

These figures are reasonable, but the unreliability of rough estimation in individual cases is shown by the fact that the column "fair amount" showed occasional variations from 0.030 to 1 per cent., only the average of a large number giving a reasonable figure. On the other hand, quite low values were at times found in the column "considerable amount," and comparatively low values even in the column "large amount."

The next step was to consider what relation, if any, existed between the amount of protein and the incidence of casts. It having been shown that the conventional expressions have a value where large numbers are concerned, it became permissible to include a further 814 cases in which the protein had not been actually measured (but only roughly estimated), with the following striking result.

Relation between Protein Content and Incidence of Casts.

Of 759 cases with a trace of protein ...	18% had casts
Of 197 with fair amount	53% ,,
Of 152 with considerable amount	49% ,,
Of 80 with large amount	77% ,,
Of 27 with very large amount	78% ,,

Rewriting in round figures we may say that 20 per cent. of cases show casts for a trace of protein; 50 per cent. for a fair amount and a considerable amount; and 80 per cent. for a large amount and a very large amount. This simple progression is very striking, though it would seem at first sight that cases showing averages of 0.050 and 0.110 per cent. protein are clinically on the same footing. On carrying the analysis further, however, so as to take into consideration the type of casts, the more serious view taken of granular casts will be seen to be justified, for the following table shows that from 0.110 per cent. protein upwards granular casts show a sudden increase at the expense of hyalogranulars.

Percentage Incidence of Types of Casts at varying Protein Content.

	0.010% Trace.	0.050% Fair Amount.	0.110% Considerable Amount.	0.440% Large Amount.	1.05% Very Large Amount.
Hyalogranular	55	63	47	43	40
Granular ...	20	19	32	33	40
Epithelial ...	5	2	7	9	20
Hyaline ...	20	16	14	15	—

The work of which these studies are the outcome was done in the Central Laboratory of the Ministry of Pensions.

OPERATIVE TREATMENT OF CIRRHOSIS OF THE LIVER.

BY

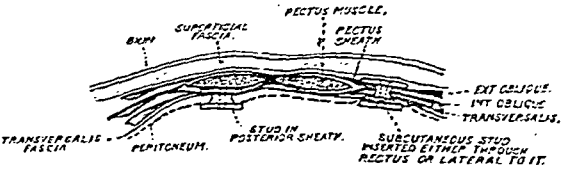
THOMAS TANNAHILL, M.B., CH.B.,

GLASGOW.

THE following case, one of alcoholic cirrhosis of the liver, in a man 70 years of age, is worthy of record principally because of the excellent result of the surgical treatment employed, the technique of which I am sure is not widely known.

Mr. X first came under my care in January, 1929, and a diagnosis of cirrhosis of the liver was made. At that time there was some free fluid in the abdominal cavity and signs of arteriosclerosis throughout the body, with gradual loss of weight and of strength. In March his condition became decidedly worse; his weight decreased rapidly, his abdomen became more distended with fluid, and a caput medusae was apparent; the daily output of urine dropped to about 20 oz. and a very grave prognosis was made.

On March 30th he was tapped and 170 oz. of fluid were withdrawn from the abdominal cavity. No improvement followed, and on April 4th Mr. G. C. Swanson of Glasgow was called in consultation. The patient was removed to a nursing home, and the following operation was performed.



A vertical incision, slightly to the right of the middle line, and extending from the ensiform cartilage above to within an inch of the umbilicus below, was made through the skin and subcutaneous tissue. The anterior sheath of the rectus was opened in the same line, the rectus pushed aside, and the abdominal cavity entered through the posterior sheath and peritoneum. On opening the abdomen bile-stained ascitic fluid welled out of the wound in large quantity.

The diagnosis was confirmed by an examination of the liver, which was typical of cirrhosis. The spleen and kidneys were not unduly affected in size.

The great omentum was drawn upwards and sutured into an opening in the upper part of the posterior sheath of the left

rectus muscle (epiplopexy), the object of this being twofold: first, in order to establish a collateral circulation or by-pass between the portal and systemic venous systems and so relieve the portal obstruction, and, secondly, in order to keep the omentum from

interfering with the second procedure adopted. The second procedure was carried out in order to cause absorption of the ascitic fluid by the lymphatic and circulatory systems. This was done by insertion of two Paterson's buttons (devised by Professor Peter Paterson of Glasgow University), one on each side of the incision. These buttons are made of smooth glass, in shape they are like collar-studs, but with both discs equal in size, and with

the stem hollow. One stud was inserted so that it made a communication between the abdominal cavity and the space underneath the anterior sheath of the left rectus; the other, between the abdominal cavity through the right rectus into the subcutaneous tissues. The studs were inserted at the level of the lower end of the incision and about two inches to either side of it, in order to keep them as far away from omentum as possible. The wound was then sutured in layers.

The after-results have been surprisingly good. From the date of the operation Mr. X has not ceased to improve. It was thought advisable to tap him once more, ten days after the operation, owing to a reaccumulation of fluid; 70 oz. were withdrawn, but since then there has been no more accumulation of fluid, and on examining him, on October 10th, I failed to detect any free fluid in the abdominal cavity. His weight had increased rapidly, sometimes 4 lb. in a week, until on the date mentioned it had reached 11 st. 8 lb. He then felt exceedingly well, and had an excellent appetite. His complexion was fresh and healthy, and his mental outlook bright and alert. In other words, the operation had "made a new man" of him.

I feel sure that an operation capable of producing such results in a condition commonly considered almost hopeless by general practitioners should be given wider publicity and further trial.

DERMATITIS ARTEFACTA DUE TO CANTHARIDES PLASTER.

BY

FREDERICK GARDINER, M.D., F.R.C.S.Ed.,

PHYSICIAN, SKIN DEPARTMENT, ROYAL INFIRMARY, EDINBURGH.

CASES of artificially produced dermatitis are always interesting, and this one is especially so, because of the agent used and the psychology of the patient and friends. The details of the case are as follows.

An unmarried woman, aged 26, had suffered from a bullous eruption on the front of the neck and the chin down to the sternum; there were also some lesions on the backs of the hands. The lesions were markedly angular and showed definite blisters in places, and I thought that heat would be a likely cause. They were reported to have persisted off and on for nine months. She had an operation for appendicitis in February, 1928, the wound remaining open until October, and the eruptions date from about that period. Menstruation had been absent for about eighteen months.

Her first doctor stated that the condition was artefact, and then he admitted that he was mistaken—at least, so the sister avers. The other doctor consulted later maintained that, in his opinion, it was artefact. She was admitted to the ward and lesions still developed, until a nurse found that she carried a handkerchief to the bathroom. In the handkerchief there were subsequently found several fly blisters; she had even put them on under starch poultices while in the ward. Later the matter was further cleared up by her sister finding fly blisters in her bed in the bedroom she had vacated at home.

When admitted to the ward she was sleepless and had a furtive expression. After the discovery of the blisters, and after the evil of her ways was pointed out to her, she was very quiet for a day or two. Thereafter she became one of the most obliging and cheerful patients in the ward.

The communications with the friends form another point of interest. When first seen, the sister, who, the doctor states, is a good housewife and mother, asked me if I thought the condition was artificially produced, and on my answering in the affirmative, she said that it was a lie. I naturally suggested that such a statement was not tolerated in the infirmary, and she was dismissed with an admonition and assurance that her sister would be well looked after. Two days later, over the 'phone, she asked me if I had found out the cause, and on my replying that blisters were ascertained to be the cause, she retorted that she would report the matter to the managers of the infirmary, and barged down the telephone. The next day, instead of carrying out her threat, she sent a letter, from which the following is extracted:

"How did you diagnose the case so quickly? My husband and I watched the blisters for six months and have not discovered their origin. Of course, you are a professional, we are not, only we have eyes. Did you personally observe blisters being put on or who observed blisters being put on? If you have found what blisters are put on with please keep same as I wish to see personally that specific article a thing. I know now that you have not seen them personally, starting and finishing, as it takes a considerable time for them to appear. Of course, if a nurse told you that she observed blisters being put on naturally you would believe her, whereas I would say she was hypnotized into believing so by some *Higher Force*, so be very careful how you treat her. I demand that my sister should be observed carefully for a considerable time. The whole trouble now is that she is aware of your suspicions. She is very sensitive, and does worry so about these silly suspicions; first one doctor says blisters are caused by boiling water, another says a poker, another suggests acids, a truly interesting case with a final suggestion of fly blisters (Cantharides). Please give her a chance before you come to conclusions.

"Pardon me if I seem impertinent, I am merely determined that my sister will have attention. I know you will be the first to do your best *when disillusioned*."

Finally, when the blisters were found not only in the ward but in her home, the sister wrote a very complete apologetic letter.

The humour of the situation will doubtless strike some readers. Evidently there are also marked psychic abnormalities in both the patient and her married sister. In the circumstances it would not have mattered if we had not been able to clinch the diagnosis so satisfactorily, but in dealing with a private patient there might have been more serious trouble and loss of kudos.

MEDICAL, SURGICAL, OBSTETRICAL.

A GENERAL METHOD FOR MALLORY'S TRIPLE STAIN.

IT is generally stated in textbooks of histology and microtomy that Mallory's connective tissue stain can only be employed successfully with material that has been fixed in Zenker's fluid or, at a pinch, with other sublimate solutions. This does not seem to be invariably the case, judging by the reports of workers with whom I have come in contact. For my own part I have found the following method to give uniformly good results with ordinary fixatives, especially as regards the fuchsine and orange components of the stain. Since most pathological materi is sent up in formol or alcohol there is no need to stre the advantages of having a routine method of renderin such amenable to the Mallory technique.

The modification consists in the use of a mordanting bath prior to immersing the sections in acid fuchsine. T make the bath prepare the following solutions:

(*a*) Potassium bichromate	3 grams
Distilled water...	100 c.cm.
(*b*) Hydrochloric acid (conc.)	10 c.cm.
Spirit	to 100 c.cm.

One part of (*b*) is mixed with three parts of (*a*) when required. The mixture should be used while fresh—within four hours; after that time the greater part of the alcohol will have been oxidized by the bichromate. Sections which have been fixed in alcohol, formol, or piero-formol (Bouin) are brought from xylol through absolute alcohol to spirit in the usual way; they are then transferred to the mordant prepared as above and left in it for five to seven minut If desired they can now be rinsed (not washed) in wat although this is unnecessary. They are then placed in t acid fuchsine solution, and the subsequent procedure is in the standard Mallory technique. Five to seven minut in each of the stains is ample time with this method. Th finished sections show the same colours and differentiation as do those made from Zenker material.

In the course of "controls" on the method given it was found that acidulated bichromate (without alcohol) was unsatisfactory. The fuchsine overstained in practically every case and the orange-G scarcely showed up at all. Probably the good results from the use of acid alcohol and bichromate, freshly mixed, are due to some "nascent" condition of the chromium element as a result of the interaction of the constituents of the mixture. Further, it was found that the best results were obtained by transferring the sections directly from spirit to mordant without intervening grades of alcohol.

It is well to remember that the preparation of the aniline blue-orange-G mixture has a great deal to do with the success of this stain. I find it a good plan to mix the powders well with a spatula after weighing. The mixture is then added slowly to the water in which the oxalic acid has previously been dissolved. The bottle should be well shaken after each small addition.

Grübler's stains were used throughout this research.

MICHAEL A. MACCONAILL,
Lecturer and Senior Demonstrator in Anatomy, University of Sheffield.

TWO CASES OF AXILLARY BREAST.

I HAVE come in contact with two cases of engorged axillary breast giving rise to pain during the puerperium, which seem of sufficient interest to put on record.

CASE I.

The patient, a 2-para, aged 23, was admitted to the maternity wards of Dundee Royal Infirmary on June 20th, 1929, and was delivered on the following day. On the second day of the puerperium she complained of pain in both axillae which kept her from moving her arms freely. On examination it was found that the axillae were occupied by swellings the size of half an orange; they were tense, very tender, and on pressure exuded milk from the pores of the skin. No tail of breast tissue stretching into the axilla could be made out by palpation, and the breast and the swelling in the axilla seemed to be separate. There was marked engorgement of both breasts, and the milk literally ran from the nipples. Treatment with axillary pad and bandage relieved the symptoms, and the pain had gone almost entirely by the seventh day. There were no supernumerary nipples.

Previous History.—Similar swellings had been present at her last confinement, but they were not so painful nor so large, and had been diagnosed as axillary adenitis. It was on this occasion that she first noticed any swelling of the axillae. She had become aware of a swelling in the armpits about the fourth month of her first pregnancy.

Family History.—The mother of the patient and one multiparous sister had had similar swellings. Two nulliparous sisters had not any.

CASE II.

A 3-para, aged 27, was delivered on September 8th, 1929, on the "district." On the third day of her puerperium she complained that she felt pain in both axillae, but worse on the left side, and pain on moving the arms. On examination a large tense swelling about the size of half an orange was found in the left axilla, and a small tense swelling about the size of a walnut in the right axilla. They were too tender to permit of pressure to see if milk exuded. There was no apparent tail connecting them with the breast. Associated with the condition was engorgement of the breasts, especially of the left breast. The swellings were treated with axillary pad and bandage, and the tenderness and pain had gone almost completely by the seventh day, and the swellings were quite soft. Incidentally, the patient felt less pain in the axillae after the baby had taken the breast. She had a temperature of 99° F. on the fourth day, probably due to breast engorgement.

Previous History.—The patient had been aware of a fullness in the axillae at the age of 15, shortly after menstruation began, but it did not trouble her until her first confinement, and recurred in each succeeding confinement in the first week of the puerperium. She noticed that the swellings got gradually bigger during pregnancy.

Family History.—The mother of the patient had similar swellings; one multiparous sister had not, and one nulliparous sister had not, but menstruation has not yet begun.

Comment.

The prominent features of the cases are as follows:

1. The swellings in the axillae are evidently breast tissue, because (*a*) they increase in size during pregnancy and at each pregnancy; (*b*) milk can be expressed from them; (*c*) of their subsidence by treating them as engorged breasts; (*d*) there is marked increase in size during lactation.

2. Although no connecting strand of breast tissue could be made out by palpation or inspection, it is probable that there is some connexion between the swelling and the breast, because of the immediate relief after suckling the child.

3. Engorgement of the breasts seems to be an accompaniment.

4. The marked familial tendency to inherit the swellings, as the mother of the patient in both cases had swellings in the axillae.

5. No nipples were present on the swellings and no supernumerary nipples were detected elsewhere on the body.

I am indebted to Professor McGibbon, under whose care these patients were, for permission to publish these two cases.

R. E. ANDERSON, B.Sc., M.B., Ch.B.,
Late Resident Obstetrical Officer, Dundee Royal Infirmary.

TREATMENT OF HAEMORRHAGIC DISEASES BY WHOLE BLOOD.

THE two cases here recorded show the value of the subcutaneous injection of whole blood in haemorrhagic diseases.

CASE I.—*Melaena Neonatorum.*

A baby, born on October 13th last, after a natural labour, developed considerable melaena on October 17th. Between 12.30 a.m. and 6 p.m. the child passed four large stools containing blood, and became extremely shocked and pale. An ounce of whole blood was given subcutaneously at 1.30 p.m., and again in the evening. However, as the haemorrhage continued, the infant was given two more injections of one ounce of blood the next day. The melaena stopped on the third day, after another subcutaneous injection had been given. Blood serum was given by the mouth in teaspoonful doses, together with salines, glucose, and breast milk. The infant has regained its colour and now appears quite normal.

It is interesting to note that this child had a temperature of 101° to 102° F. during the illness, which persisted for seven days after cessation of the haemorrhage. This is said to point to an infective origin of this obscure disease. As three direct blood relations of the infant have died from pernicious anaemia, there may possibly be some connexion with this condition.

CASE 2.—*Haemophilia.*

This patient, a man aged 37, had been suffering from haematuria, melaena, and bleeding from the gums for seven days before he came under my care. He was ordered calcium lactate, calcium injections, haemoplastin, horse serum, glucose, and rectal salines. The blood loss was worse next day and the patient became almost moribund, with rapid thready pulse, extreme pallor, sweating, and air hunger. He was given 25 c.cm. whole blood into the gluteal region at 9 a.m., and by 1 p.m. the haematuria had ceased and his general condition had greatly improved. From that time the haemorrhage ceased altogether, and he has been free for nine months.

It is of interest to note that in the first case a large quantity of blood was required, and only a relatively small amount for the haemophilia.

HAROLD PEREIRA, M.R.C.S.
ARTHUR PEREIRA, M.R.C.S.
London, N.10.

Reports of Societies.

SURGICAL TREATMENT OF PULMONARY TUBERCULOSIS.

AT a meeting of the Medical Society of London, on February 10th, with Mr. DONALD J. ARMOUR in the chair, a discussion on the surgical treatment of pulmonary tuberculosis was opened by Dr. GUSTAVE MAURER of Davos, who demonstrated the method he used combining diathermy current and the electro-cautery.

Dr. MAURER described his method of dividing adhesions by galvano-cauterization under the guidance of the thoracoscope, with preliminary diathermy to obtain tissue coagulation. He classified adhesions into four categories: those in which neither the pulmonary nor the thoracic insertion was broadened out; those in which the thoracic end only was broadened; those with a conical expansion of the pulmonary insertion; and hour-glass adhesions in which both insertions were expanded. He discussed the possible dangers and the relative value of the cautery in each. The decision with regard to pneumolysis must depend upon a proper thoracoscopic interpretation of the adhesions. For the purpose of probing from the point of entry it was his practice to use a Saugman needle provided with a bored olive-shaped indicator which could be slipped over the point of the needle, and was so smooth as to move up and down the needle easily. He first introduced the needle at a right angle to the chest wall at the point chosen for thoracoscopy, at the same time moving the indicator forward. During the process of pushing the needle further into the pleural space, on encountering an adhesion of the lung itself the indicator was pressed back, and the distance of the obstacle from the skin could then be measured. Saugman's needle was thereupon withdrawn some centimetres and reintroduced in all directions in succession, thus giving approximately exact information about the conditions in the pleural space. Dr. Maurer expressed himself strongly against the use of a cutting diathermy, which was

a fruitful cause of empyema. It was his own practice to employ high-frequency currents of 0.1 to 0.3 ampere, which were quite sufficient to ensure a sharply defined area of coagulation in the tissues. With this strength of current the tissue was never divided, and deep coagulation did not occur. In the case of string adhesions, he made a continuous coagulation sleeve around the thoracic insertion, and in the case of sail-like adhesions a coagulation line; these sleeves and lines should be about 3 to 4 mm. wide. The time spent on the preparatory coagulation was quickly made up during the galvano-cauterization, since the cautery could now be used at red heat without danger. The risk of haemorrhage was averted by this combined method, that of empyema was reduced, it was possible to divide adhesions at the thoracic insertion, and the field of operation was enlarged. In 130 cases operated on by this method only one patient developed empyema, and one tuberculous exudate; there was no death directly or indirectly resulting. The cautery should be so introduced that its loop could be placed as nearly as possible at right angles to the thoracic insertion of the main adhesion. The galvanic current was regulated so that the tip of the platinum loop just showed a red glow. This feebly heated loop clung well to the tissues, and was therefore pressed hard against the diaphragmatic end of the adhesion; it fixed itself at once to that position. As soon as the guiding hand had accustomed itself to the respiratory rhythm a strong current was switched on, and the loop then made a deep furrow in the adhesion. Dr. Maurer showed colour slides and *x*-ray photographs of typical cases.

Mr. MORRISTON DAVIES said that when collapse of the lung was necessary the simplest, if not the easiest, procedure was artificial pneumothorax, and when it could be employed it was undoubtedly the best surgical method in uncomplicated cases. Complications were frequent, however, and other forms of surgical treatment had to be considered. The first of these was phrenic evulsion, a relatively simple operation designed to secure hemidiaphragmatic paralysis. The indications for this method were cases of purely basal tuberculosis, of basal pleurisy, especially with thickened pleura, and also cases of generalized tuberculosis in which pneumothorax had failed and a more extensive operation was contraindicated. One of the great drawbacks of pneumothorax was that the lung was constantly expanding between each refill, but with thoracoplasty the collapse, once produced, was permanent. It was not necessary in every case, unless there were cavities in the lung or dilatations of the bronchi, to obtain a complete collapse in order to bring about healing. In many cases what was wanted was a partial collapse with immobilization and resting of the lung. Thoracoplasty should not necessarily be a rigid eleven-rib operation as originally suggested; there were many cases in which thoracoplasty with excision of parts of the first eight, or seven, or even six, would result in sufficient collapse to produce the healing effect on the lung. The indications for thoracoplasty were, in the main, those for artificial pneumothorax, but, except in one set of cases, thoracoplasty should not be employed until pneumothorax had been tried and had failed. The one type of case in which a thoracoplasty was indicated in preference to pneumothorax was the old long-standing type, where the mechanical changes in the lung, with extensive dilatation of all the tubes, were the predominant trouble and not the tuberculosis. The contraindications for thoracoplasty were much stronger than those for pneumothorax. In pneumothorax the presence of activity in the opposite lung did not necessarily preclude it, but in thoracoplasty it should be an absolute contraindication except in cases of persistent and uncontrollable haemorrhage endangering the patient's life.

Dr. F. G. CHANDLER remarked that artificial pneumothorax was one of the most effective methods of treatment, but even to-day many members of the profession neglected it. The effectiveness of artificial pneumothorax was to a large extent dependent on its completeness. With regard to internal operations, Mr. Morriston Davies's first essays in adhesion-cutting by means of a tenotome with the patient on the *x*-ray table had historical interest, but it was too dangerous to become a routine procedure. Later, Jacobeus interested the medical world with his endoscopic methods. That there were difficulties with these, especially in respect to orientation, was proved by the numerous modifications made of the original instrument. Then the diathermy current had been introduced, and Dr. Maurer had adopted a very ingenious method of electro-cauterization; but it involved two openings, and to many workers it would seem very desirable to carry out the whole operation through one opening. Dr. Chandler exhibited an instrument which he had modified from an American pattern; it involved only one puncture. The field of vision for the thoracoscope in this arrangement was excellent; it was almost direct, being only 30 degrees off the axis, thus simplifying orientation. Diathermy current was employed, absolutely under the control of the operator by means of a foot-switch; with a large electrode coagulation was obtained, and so the risk of haemorrhage was minimized. He had operated on seventeen patients, and had had no unfavourable reactions. Dr. Chandler added a few words about the procedure of oleothorax; the chief indication for which was obliterative pleurisy.

Mr. TUDOR EDWARDS said that the division of adhesions in this country was usually carried out with a modification of the instrument of Jacobeus; he had not found it so difficult to use as Dr. Chandler had suggested. The risk in using diathermy as a means of cauterizing before division arose from the absence of control over the extension of the coagulation into the bands. All chest surgeons attempted to divide the bands as near the pleura as possible, however long or narrow the adhesion might be. There was, however, a danger in dividing an adhesion so close to the pleura at the apex as Dr. Maurer had advised. The speaker was not quite happy about the value of partial thoracoplasty, which in his view resulted in a considerable limitation of the degree of collapse, as compared with the amount of rib removed. Unless the thoracic cage were divided completely collapse would be greatly limited. Mr. J. E. H. ROBERTS pointed out that Mr. Morriston Davies had not mentioned the great difficulty arising in phrenic evulsion from the presence of the lymphatic glands. He had seen several cases where the lymphatic glands were extensive, and in pushing these aside the vessels were torn, and local effusions in the neck had resulted. He was not very much in favour of partial collapse, and he also preferred, in the majority of cases, to perform thoracoplasty in stages.

Dr. MAURER, in reply, praised Dr. Chandler's instrument as being the best he had seen for single puncture: his own method, which involved a more extensive operation, necessitated two punctures.

INTRATHORACIC TUMOURS.

A special discussion on intrathoracic tumours was held at a meeting of the Section of Surgery of the Royal Society of Medicine on February 5th, with Sir HOLBURT WARING in the chair.

Mr. A. TUDOR EDWARDS opened by asking whether the apparently growing incidence of primary malignant disease in the thoracic cavity represented a true increase, or was due to the more exact diagnosis which had become possible. The greater number of cases of benign growth reported would suggest that the diagnostic factor was partly responsible. Intrathoracic tumours might be classified as mediastinal, pulmonary, or pleural, according to the site of their origin. Benign mediastinal tumours comprised intrathoracic goitres, mediastinal dermoids, and teratomas. The earliest and most characteristic symptom of intrathoracic goitre was dyspnoea, constant in some cases and paroxysmal in others. The physical signs included an area of dullness of varying extent on percussion over the sternum, and also the presence of large dilated veins; *x*-ray examination showed a well-defined opacity in the upper substernal arch. Mediastinal dermoids and teratomas never gave rise to symptoms due to their mediastinal position, although when they extended outwards quite distinct symptoms made their appearance. Intrathoracic goitres should be removed as soon as symptoms of interference with respiration intervened. The speaker gave an account of the operative exposures, and said that he had operated on seven cases of intrathoracic goitre, with one

post-operative death, the necropsy disclosing an enlarged thymus. With regard to mediastinal tumours, an operation was rarely possible, and, even when performed, freedom from recurrence was unusual. The majority of cases of sarcoma in the mediastinum were inoperable, and should be treated by radium. He had been disappointed with the results of deep x-ray therapy.

Passing to pulmonary tumours, Mr. Tudor Edwards remarked that benign tumours were extremely rare. Dermoid of the lung had been reported, but it had probably originated in the mediastinum and burrowed into the lung. The most common cyst was the hydatid, which might be single or multiple. Primary carcinoma might arise in the bronchi or the alveoli. Sarcoma was much rarer in this situation than carcinoma. In bronchial carcinoma dyspnoea appeared to be the earliest and predominant symptom. Endothelioma occasionally arose as a central growth, and could be differentiated from carcinoma only by microscopical examination. Bronchial carcinoma only rarely allowed of radical extirpation; he had yet to see any great improvement, still less any cure, result from deep x-ray therapy. It was too early to say whether radon seeds led to a definite disappearance of the growth, but there was such an improvement as to warrant a trial. Central carcinoma and endothelioma offered a much better chance for operative treatment: with secondary deposits in the lung, treatment would rarely be of any value. Pleural tumours gave rise to symptoms of pain and irritative cough. An x-ray examination would confirm the diagnosis of tumour, and the clear outline would distinguish the growth from infiltrating tumours. Surgical removal should be advocated, if the general state of the patient permitted, as soon as the diagnosis was made. As regards malignant tumours in the pleura, endothelioma might be localized or diffused, the latter being the more common. Localized thoracic pain was the most frequent symptom. The physical signs were those of pleural effusion, always haemorrhagic in the later stages. A localized growth might be removed if diagnosed before secondary deposits made themselves evident. In conclusion, Mr. Edwards said that in spite of modern aids to diagnosis there would remain a proportion of cases in which exact diagnosis was impossible, and in these cases exploratory thoracotomy should be performed. If certain precautions were taken, this procedure was no more serious than exploratory laparotomy, and convalescence was shorter. In the case of benign intrathoracic tumours, it should be borne in mind that these would destroy life by pressure on vital structures within the thorax.

Mr. W. H. C. ROMANIS limited his remarks to four classes of tumours: goitres, dermoids, hydatids, and malignant growths of the lung. Surgeons were accustomed to see cases of Graves's disease with large extensions of thyroid tissue down behind the sternum; also, more rarely, they saw the so-called plunging goitre, which was situated in the neck, but moved up and down in the chest as the patient coughed or swallowed. The real thoracic condition was a mass of thyroid tissue deep down inside the chest. One important diagnostic possibility should be borne in mind. In an x-ray photograph there might be a rounded shadow just below the sternal arch; if it was remembered that this might be a retrosternal goitre there was less liability to miss many of them. Retrosternal goitres could be very easy to remove, or the reverse. The speaker had only found it necessary to split the sternum once, but he would have no hesitation in doing this if it was required. One of the most interesting features of dermoids was the variety of manifestations to which they gave rise; the main symptom sometimes was the bringing up of sputum. For removal he had little doubt that the best approach was from the side, making a large incision between two ribs. Hydatids were rare in this country; here the chief precaution was to bear in mind that it was just as deleterious to let out into the pleura the contents of a hydatid cyst as it was to let out pus, and something must be done to shut off the pleura. The old warning against putting needles into hydatid cysts in the lung had quite a sound foundation. With regard to malignant growths in the lung, the percentage of operable cases that any surgeon saw was lamentably small. The speaker, though not altogether a radium enthusiast, had had the opportunity of trying radon seeds on growths in the lung, with certainly beneficial effects in a number of cases. He had one case at present classifiable as a surgical failure but a radium success. There would be a fair number of good results with radium, but for the present it appeared to be better to use radon seeds rather than radium itself, because in that way the difficulty of taking the material out afterwards was obviated. With regard to exploratory thoracotomy, one procedure before operation which he regarded as essential was the production of artificial pneumothorax.

Dr. L. S. T. BURRELL suggested as a rough classification: (1) benign tumours, such as fibroma and dermoid; and (2) malignant cases, including endothelioma of the pleura, carcinoma of the lung, and sarcoma of the mediastinum. The most common symptoms numbered three: pleural effusion; pressure, including pressure on the bronchus, which might occur rather suddenly; and haemoptysis as the initial manifestation. With regard to diagnosis, the patient with a neoplasm did not have any constitutional symptoms, or very few, thus contrasting with tuberculosis. The great majority of these cases were diagnosed by x-ray examinations, which would reveal a tumour in some instances, but more commonly collapse of lung as a result of the tumour. Sometimes it was difficult to tell which shadow indicated collapse and which the actual tumour. When there was effusion with tumours it was often blood-stained, but a more important sign was an excess of endothelial cells when one would have expected small lymphocytes on the assumption that a chronic infection was present. It was very important to have the x-ray photograph taken from the lateral as well as from the antero-posterior point of view. Dr. Burrell emphasized the importance of injecting lipiodol; many of these tumours produced symptoms by blocking the bronchus. He agreed as to the importance of preliminary artificial pneumothorax, which would show whether the tumour was inside the lung or not, and enable a thoracoscope to be introduced into the chest, thus establishing the diagnosis beyond doubt. In his opinion there was only one treatment for these cases, and that was surgical—the sole chance of saving the life of a patient with malignant disease of the chest. He had had several patients who had improved as a result of deep x-ray therapy, but in every single instance there had been recurrence. He thought that in time radium might be a cure for neoplasms in general, but at present, in his experience, it was absolutely useless in any case of intrathoracic growth. The size of the growth need not deter the surgeon.

Dr. F. G. CHANDLER showed a number of lantern slides illustrating some of the conditions in a slightly unusual form. He said that primary malignant tumour of the chest was common, but the evidence suggesting that it was now more common than previously was fallacious; the diagnosis of chest diseases generally had become more accurate during the last ten or twenty years. Primary malignant growths might arise in the mediastinal glands as sarcoma, in the walls of the bronchi as carcinoma, and, very rarely indeed, in the pleura as endothelioma. They might be difficult to diagnose in the early stages, and also in their later stages because of breaking down. The surest means of diagnosis were (1) x-ray examination as soon as possible; (2) bacteriological investigation to exclude tubercle bacilli; and (3) bronchoscopy. Innocent tumours should be dealt with surgically if they were causing symptoms and growing in size. The treatment of intrathoracic malignant tumours resolved itself into: x-ray therapy, radium therapy, surgical removal, and relief of symptoms. The greatest hope in lung carcinoma was early removal. The medical practitioner must be quite frank with his patients if there was the slightest chance for them, for in certain cases the boldest surgery and the biggest risk were advisable, and the patient's co-operation was, as a rule, readily forthcoming.

Mr. W. H. WHITE stated that the most frequent condition to be dealt with was carcinoma of the lung; the inoperable type was the most usual, and the commonest symptoms were the dry unproductive cough and the cyanosis associated with such attacks. He thought that some error was often made when radium was implanted into the lung, the technique of implantation being such as to cause

dissemination of cells. He described a device he had made for the purpose in which diathermy was used to coagulate the tissues on implantation, so that there was no oozing of blood and no cell dissemination. The speaker was also of opinion that the opening of the thorax under spinal anaesthesia was to be recommended.

Dr. JAMES MAXWELL said that as a result of an investigation of 184 cases of primary bronchial carcinoma, which had been collected at St. Bartholomew's Hospital and at the Royal Chest Hospital, it seemed possible to place the cases from the pathological point of view in four groups. In the first group (6 per cent.) the growth started in the root of the lung, surrounding or infiltrating the bronchus, and that alone; that type was not prone to metastasis. In the second group (20 per cent.) there was infiltration of the lobe of the lung alone; cases in this group were amenable to treatment fairly easily, and radium or x rays would be the probable method of treatment for the next few years. In the third group (25 per cent.) there was infiltration of the mediastinum, but not of the lung, and the pericardium was always involved early. This condition would never come within the scope of surgery, though it might possibly enter that of radium therapy. In the fourth type there was infiltration both in the lung and in the mediastinum; this was the commonest condition, and by far the most difficult to treat. With regard to methods of treatment, in carcinoma of the first group the intrabronchial application of radium seemed to be helpful. He had seen several cases recently in which x-ray treatment had caused the growth to metastasize far more readily than it would otherwise have done. He was not at all convinced that x rays were of use, or that they prolonged life.

Mr. J. E. H. ROBERTS said that he also had never seen any case of carcinoma of the lung which had received permanent benefit from x rays; on the other hand, he thought that there was going to be a field for radium, because the majority of cases of primary carcinoma of the lung, at the time when first seen, were certainly inoperable. He did not see how that condition of affairs was going to be altered. The condition was already inoperable at the time the patient went to see his first doctor. Not enough was known as yet about the effect of radium on normal lung tissue, nor what thickness of screening might be necessary. He had no doubt that radium, in cases in which he had applied it, had had a permanently beneficial effect, though in no case could he yet say that it had cured the patient. With regard to sarcoma, the primary condition in many cases had disappeared completely after insertion of radium, and although the patient had died subsequently of metastasis, the primary growth had not recurred.

ANAESTHESIA IN THORACIC SURGERY.

AT a meeting of the Anaesthetic Section of the Royal Society of Medicine, on February 7th, with Dr. R. E. APPERLY in the chair, Dr. C. LANGTON HEWER opened a discussion on anaesthesia in thoracic surgery.

Dr. Hewer said that it was largely owing to the diminution in anaesthetic risk brought about by improvement in anaesthetic methods that the field of thoracic surgery had been enlarged and extended so rapidly of recent years. Starting with the preparation of the patient for operation, drastic purgation was to be avoided, and plenty of fluid should be given between meals. In this way circulating toxins were diluted. Glucose could be administered with advantage. Small quantities of hypnotics could be given to adults, such as morphine gr. 1/4 and hyoscine gr. 1/100 to an adult man, with lesser quantities to women. He next touched on after-treatment. An important thing was the administration of relatively large quantities of saline, or saline and glucose, while the patient was still in an unconscious condition, given at a temperature of 115° F. One of the essential conditions in avoiding post-operative shock was the maintenance of heat. In hospital wards electric cradles or electrically heated blankets were of the greatest use, and replaced hot-water bottles with advantage. Patients were best treated in small rooms, which could be easily heated, and he pleaded for the installation of small recovery rooms, preferably adjacent to the theatre, in all hospitals. Important anaesthetic problems arose in connexion with thoracic surgery. The patients, as a rule, were in poor general condition, suffering from conditions such as phthisis, tumour, or bronchiectasis. The chest wall was vascular, which meant increased risk of shock. Pressure relationships in the lungs were interfered with, and had to be regulated by the anaesthetist. The anaesthetic should have no depressant effect on the normal lung tissue; (3) the cough reflex should not be abolished; (4) recovery should be rapid; (5) the anaesthetic should be able to be administered when one or both cavities of the lung were opened; and (6) oxygenation should be adequate even when these cavities were opened.

Local analgesia by infiltration, paravertebral block, etc., was useful in some types of cases, and after-effects were rare, except that pain seemed to be increased. The coughing reflex was not abolished, though its efficacy might be impaired to some extent. Pleural shock, however, existed, and might lead to general shock. There was also some danger of toxic symptoms occurring if large quantities of drugs, such as novocain and adrenaline, were injected, and there was a risk of heart failure if the solution got directly into a vein. The great disadvantage of the local method was, however, that there was no protection against lung collapse or respiratory obstruction. Chloroform had a definite place in thoracic surgery, especially during induction. Its disadvantages were the abolition of the cough reflex, the possibility of vomiting, and the slow recovery. Ether in quantity was disadvantageous, but could be used by the open method in small quantity, and possibly added in minimal quantity to nitrous oxide and oxygen. Paraldehyde and avertin gave rise to post-operative depression. Nitrous oxide and oxygen, having no immediate deleterious effects, being non-irritating, and causing no marked increase of saliva or mucus, was the anaesthetic of choice in thoracic surgery. It had usually no after-effects, and, if vomiting occurred, it was usually due to causes other than the anaesthetic. The poor muscular relaxation accorded by this combination was of small importance in thoracic surgery. Ethylene and oxygen could be used in the same way as nitrous oxide and oxygen. Its only advantages were that it gave slightly better relaxation, and could be used with slightly higher oxygen percentages. It had three great drawbacks: its unpleasant smell, the subsequent nausea it caused, and its high explosiveness. Acetylene behaved in much the same way as ethylene, and had much the same disadvantages.

In superficial operations upon the thoracic wall, including carcinoma of the breast, the choice of anaesthetic was not of great importance. When the whole thickness of the chest wall was involved the best anaesthetic was nitrous oxide and oxygen. This could be given with an ordinary gas mask and the pressure of oxygen and nitrous oxide regulated by any suitable machine. When the thoracic wall was opened a positive pressure up to 10 mm. of mercury was an advantage. Where one pleural cavity was to be opened the use of differential pressure was essential. Endotracheal insufflation was of use in some cases, but was often unnecessary, and in a few cases a positive disadvantage. Where the trachea was much deformed by the pressure of a growth the passage of the tube, while immediately effective, later was a disadvantage, in that on its withdrawal the trachea might collapse and lead to obstruction, or the passage of the tube might lead to such swelling that on its withdrawal complete occlusion of the lumen of the distorted trachea might result. The anaesthetist should therefore use a well-fitting face-piece on a gas and oxygen apparatus, and have all apparatus ready at hand to pass an endotracheal or intranasal tube, should such be necessary. Dr. Hewer disclaimed anything original in his communication, but hoped that it would lead to animated discussion.

Dr. IVAN W. MAGILL preferred to divide the operations into two groups. In the first were the superficial cases where a positive pressure was not absolutely necessary. In the second group were the tumours, retrosternal goitres, and removal of larynx. In these cases it was as well to

induce a pneumothorax beforehand so that the sound lung could accommodate itself to the changed conditions. In many cases, however, a positive pressure was essential. For minor operations local anaesthesia was best, and it might be employed for major operations also, but, for these, combined local and general anaesthesia was probably best. In most cases ether and chloroform could be dispensed with; and face-piece administration was better than endotracheal. In the second group, when dealing with tumours, intubation and insufflation usually gave the best results. The best anaesthetic was nitrous oxide-oxygen and perhaps a minimal amount of ether. Immediate recovery was not always advantageous. In conclusion, Dr. Magill summarized his opinions as follows. Local anaesthesia was best for minor operations; nitrous oxide and oxygen with intercostal nerve block for major cases. Endotracheal insufflation was to be used in selected cases only.

Mr. TUDOR EDWARDS, speaking as a surgeon, in general supported the statements of the openers of the discussion. He thought local anaesthesia best for superficial operations such as empyema and abscess. Strong positive pressure was necessary only in cases where both pleurae were opened at the same time, which was a rare event. The thoracic surgeon had the advantage that the viscera tended to fall away when the cavity was opened, instead of the reverse happening as in abdominal surgery. It was thus possible to view the chest contents under an anaesthesia much lighter than would be the case in the abdomen.

Mr. J. E. H. ROBERTS, speaking also as a surgeon, said that the anaesthetist should be familiar with serious thoracic cases. He agreed that nitrous oxide and oxygen was the best anaesthetic. Ether in quantity was prejudicial to patients. As regards local infiltration he differed from other speakers. It was unnecessary and was followed by more after-pain, and, moreover, the cough reflex was interfered with. Intratracheal insufflation was unnecessary except where great pressure is needed, as when the opposite lung is opened.

Mr. T. P. DUNHILL made a plea for the use of chloroform in suitable cases. He also pleaded for proper apparatus for the anaesthetist. It was impossible to do complicated surgery with primitive anaesthesia. Dr. F. T. EVANS did not like chloroform on account of its liability to cause prolonged sickness. In cases such as substernal goitres it was the anaesthetic of choice. Dr. Z. MENNELL believed that cases should be divided into two classes. In the first an artificial pneumothorax was produced at the outset. In the second adhesions were present which prevented the pneumothorax being produced. For the first class light intratracheal ether anaesthesia was suitable. In the second class ether was contraindicated and intratracheal anaesthesia was not essential. Chloroform to the obstetrical degree was suitable. He believed that there was a bigger field in sight for local analgesia in chest surgery, especially if speed in operating were cultivated.

Mr. H. E. G. BOYLE was in reminiscent mood, and recounted some of the demonstrations given by Meltzer at a meeting of the Section many years ago. He also pleaded for better team work between surgeon and anaesthetist.

The PRESIDENT referred to the after-pain following novocain injections for intercostal block.

ABSCESS OF THE BRAIN.

DR. HEINRICH NEUMANN, professor of otology in the University of Vienna, was the principal speaker at a discussion on brain abscesses in the Section of Otology of the Royal Society of Medicine on February 7th. The president of the Section, Mr. W. M. MOLLISON, was in the chair.

Professor NEUMANN began with a reference to Macewen's fundamental work on this subject, and his extraordinary percentage (about 80) of successful results on operation. Such a level of success had not been reached by later workers on the Continent. In the speaker's clinic there had been operations during the last ten years on 47 cases of temporal lobe abscess, with healing only in 16; the remaining 31 patients had died. Other clinics had recorded similar figures. This was the more astonishing because otology had made great progress both in diagnosis and in operative technique. It was true that Macewen operated on selected material, but even excluding from his own list the cases which Macewen would have excluded, he had below 50 per cent. of successes. The same difference occurred in cerebellar abscess; out of 27 cases the speaker had succeeded in obtaining healing only in 2. Macewen operated on abscesses without waiting for the characteristic cerebellar symptoms, such as nystagmus. More recent workers, on the other hand, believing in the value of the symptoms described in modern neurology, had underestimated and neglected the general symptoms. Professor Neumann's study of brain abscess had led him to the conclusion that the focal symptoms were relatively late in appearing, and that it was not wise to wait for them. Puncture should be made as soon as, from the general state of the patient, it seemed likely that abscess was present. The study of cerebellar abscess showed that nearly all cases began with symptoms which, seen retrospectively, should have led the clinician from the very beginning to suppose that an abscess was present, even in the absence of the specific symptoms which appeared later, or in some rare cases not at all. The study of his own cases had led him to pay great attention to general symptoms. All his patients with cerebellar abscess, for example, had complained of dizziness from the beginning, while constant occipital headache was found in nearly all cases. The most reliable diagnostic help in brain abscess was a positive puncture; in future, to verify his diagnosis based on general symptoms only, he intended to puncture at an earlier stage. The possible dangers of puncture had hindered its employment, but this consideration was not always justified. The surgical treatment of brain and cerebellar abscess must be varied to suit the individual case. Study of the pathological anatomy proved that each abscess needed its special method of operation, and that a uniform treatment could never be successful. Some recent work of Lemaitre and certain Danish clinics pointed to the employment of filiform drainage tubes. The speaker had tried to treat a few cases by this method, but he had to fall back on his old plan of stretching, plugging, or making a contra-incision. The filiform drain, placed in the abscess after the puncture, worked well at first, but in the course of treatment it proved insufficient, probably as a result of the changed conditions of circulation and tension in the brain and spinal fluid. At present the healing of an abscess must not be looked upon as a definite condition. There was not sufficient tissue material for the solid cicatrization of a great defect in brain substance, so that it was possible for one part of the resulting cavity to heal as a solid mass, while another part formed a cyst, which cyst, sooner or later, even after years, might be reinfected by an acute exacerbation, and so there occurred what must be regarded as a relapse of the abscess. In all complications of the brain the effort should be made to perform the operation in such a way that not only was the life of the patient saved, but he was prevented from permanent crippling; at the same time, in such a dangerous condition it was a mistake to operate too timidly.

Mr. HUGH CAIRNS, dealing with the subject from the point of view of the neurological surgeon, remarked that the methods of diagnosis rather than of surgery were faulty. Success in treatment depended in the first instance on the power of the brain to localize the infection. The brain had very good powers in this respect, not only with regard to its own connective tissue, the microglia, but also to the mesoglia, the common connective tissue of the body. The symptomatology of brain abscess was not yet clearly defined. Some mistakes in diagnosis might be assigned to neglect of the ophthalmoscope and perimeter. Mistakes might also arise from the too frequent conception that brain abscess must produce a high temperature, whereas in the majority of cases there was a subnormal temperature for the most part. The partially subsiding abscess during convalescence should be carefully watched; it was like a volcano, liable to erupt rapidly. Sometimes the onset of an abscess was clearly signalled by an easily distinguishable symptom, such as a Jacksonian fit; more often, however, the time of onset was uncertain, and one could not always be sure that there had not been some intracerebral infection before the onset of the illness. In temporo-sphenoidal

abscess repeated daily perimetry was important. As for localizing signs, the difficulty was to elicit them on account of the drowsiness of the patient. One useful resort was *x*-ray examination, for the abscess very often contained gas, which was revealed by *x* rays. The speaker added a few remarks on exploratory puncture of the brain—the only way in which a number of these conditions could be differentiated in the present state of knowledge. One point of negative evidence was notable; if pus was found when a very little cut was made in the dura, it was almost certain that there was not a brain abscess. Purulent pachymeningitis, from pus in the subdural space, might sometimes follow mastoiditis, and produce symptoms identical with those of temporo-sphenoidal abscess. Serous meningitis or arachnoiditis was sometimes confused with cerebellar abscess. Finally, diagnosis must be continued during treatment. The operation required often to be performed in stages; there was a right and a wrong way to operate in each case. In no disease was repeated clinical investigation more important than in abscess of the brain.

Mr. J. S. FRASER described in detail 17 cases of temporal lobe abscess on which he had operated during the last twenty years; 10 of the patients were males and 7 were females, and most of them were under the age of 30. The right side was affected in 9, and the left in 8; in only 3 cases was there otitis media. The labyrinth was functioning in 13, was negative in 2, and in the other 2 cases it was not examined. Headache was a marked feature in 15, and vomiting in 13; the temperature on admission was subnormal in 7, normal in 2, and fever was present in 8. The pulse was slow in 5 and rapid in 8. Two patients were drowsy or even comatose on admission; in 4 slight delirium alternated with drowsiness. Six patients had meningitis on admission, of whom 5 died. The total results were 6 recoveries, 11 deaths.

Mr. E. MILES ATKINSON spoke of the pathology of adjacent brain abscess. The essential point at issue in the pathology of this condition, he said, was the route by which infection entered the brain substance. He described, with the aid of graphs and sections, the distribution and direction of the vessels in the brain, and in particular pointed out the layer of white matter left behind by the central and cortical vessels after passing through the cortex and up through the base of the brain—which he termed an avascular zone. It was in this area poorly supplied with blood that the abscess made its first appearance. Of the three channels by which infection entered the brain the perivascular route was the most common; this was the route in 8 out of 14 cases he had investigated. The second was the venous route, perhaps most likely to be taken in connexion with a lateral sinus thrombosis; the third was the arterial route. If the artery was caught up by thrombosis a small embolus might be shut off and cause an abscess. The speaker touched on capsule formation—criticizing the term "capsule" as a misnomer, for all that was meant was the wall of the abscess cavity, which differed in no respect from the wall of an abscess in any other part of the body. He believed that if the mortality of this condition was to be diminished, surgeons must be prepared to explore the brain on much less evidence than that insisted upon up to the present.

Dr. W. H. JEWELL, Mr. A. D. SHARP, and other members described cases, but discussion had to be curtailed owing to the lateness of the hour, and Professor NEUMANN contented himself, in reply, with saying what pleasure it had given him to discuss these points with the inheritors of the Macewen tradition.

CARDIAC SYMPTOMS WITHOUT MURMUR.

THE annual meeting of the Devon and Exeter Medico-Chirurgical Society was held on January 23rd, with the newly elected president, Dr. F. A. ROPER, in the chair. Dr. G. L. THORNTON read a paper entitled "The heart without murmur."

Dr. Thornton opened with a warning against the too-ready dismissal of symptoms which suggested cardiac disease, even though no heart murmurs were present, and there was no evidence of enlargement or displacement of the heart, or of definite arrhythmia. He suggested a classification into seven groups of the alleged or inferred causes of conditions which gave rise to symptoms rightly or wrongly referable to the heart. These groups were: (1) cases in which the symptoms were referable to affections more or less remote from the heart; (2) cases with a history of strain but without a primary cause; (3) cases associated with hyperthyroidism; (4) cases associated with neurasthenia, but without hyperthyroidism; (5) acute or chronic cases of myocardial affections; (6) cases of mechanical embarrassment, as in nephritis with high blood pressure, hyperpiesia without nephritis, and chronic bronchitis and emphysema; and (7) cases of valvular disease of the heart where the murmur only became audible later in the history. Examples were given to illustrate these various groups as they had occurred in general practice, or under the conditions of active service during the war, or as sequels of such service. Dr. Thornton paid a tribute to the value of the wooden stethoscope in affording valuable information in doubtful cases. He had also found the differential stethoscope very helpful in myocardial cases to detect the first signs of cardiac abnormality, and to enable a prognosis to be given both at the first examination and during subsequent treatment. Recognition of a low systolic blood pressure was also helpful in revealing any progressive myocardial failure in advanced valvular disease, or in clinching an early diagnosis of degeneration of the myocardium. The speaker emphasized the point that diagnosis and prognosis could only be based on the sum of all the subjective and objective findings. In some cases the patients had been discharged from the army with a diagnosis of cardiac embarrassment, when they were really suffering from early pulmonary tuberculosis. In the course of some references to treatment Dr. Thornton remarked that as regards the labouring classes it was often very difficult to find suitable employment for patients with cardiac disease, many of whom were obliged to return to work under unsuitable conditions. He thought it should be possible when big employment schemes were launched at the public expense for the less technical work to be graded so as to offer openings for those who were not physically strong. He added that both diagnosis and prognosis would be made more certain in the future if a minute examination of the heart was conducted by a pathologist in all cases of sudden death.

The PRESIDENT discussed present views in regard to the significance of apical and precordial systolic murmurs, and the necessity for seeking concomitant signs and symptoms before assessing them as of valvular ill omen. His experience had coincided with that of Dr. Thornton in respect of many men discharged from the services with a diagnosis of disordered heart action, pulmonary tuberculosis having proved eventually to be the true interpretation of their symptoms. Touching on strain he said he had had personal experience of a case where over-exertion at a game had proved to be the immediate provocative cause of auricular fibrillation in a young girl in whose previous history there could not be discovered rheumatism or any acute fever of a predisposing nature. From his experience on medical boards Dr. Roper also testified to the elusive character of the diastolic murmur in aortic disease as pointed out by Dr. Thornton.

Dr. R. V. SOLLY mentioned that the late Dr. William Gordon had attached importance to a modified form of the old wooden stethoscope as a means of control auscultation in cases where a murmur was inaudible in a suspect case of valvular disease. Mr. NORMAN LOCK, speaking from the point of view of an operating surgeon, asked if there were any cardiac conditions which could at once be stated as contraindicating surgical intervention. Dr. GIDLEY mentioned the sudden heart failure which so often occurred in cases of malignant disease where a normal pulse rate with regular rhythm had given no preliminary warning.

Dr. THORNTON, replying, said that where the myocardium was suspect, and there was a low reading in the systolic blood pressure, a clear case was made out for due estimation of the patient's outlook, if operation were abandoned, as compared with the immediate risk during the operation in question. It had to be admitted, however, that many patients survived severe and prolonged emergency operations in spite of cardiac conditions which would have caused considerable hesitation in other circumstances.

Reviews.

RICKETS, OSTEOMALACIA, AND TETANY.

IT would be difficult to find anyone more fitted than Dr. ALFRED F. HESS to write a book on *Rickets, including Osteomalacia, and Tetany*.[1] He is a clinician of high repute, an investigator of standing, and an active participant in the fight made during the past ten years to obtain more insight into the etiology of rickets and its allied disorders. Dr. Hess has changed his views about these disorders, for at one time he was opposed to the present writer on the question of the dominating part played in their production by the antirachitic vitamin, or "factor" as he prefers to call it; even as regards the curative effect of ultra-violet radiations on rickets he is a convert. The experience of conversion, in medicine as in some well-known non-scientific subjects, seems to ensure success in the writing of books, for Dr. Hess's book is certainly an excellent production. Its style is most attractive; modern work is, on the whole, well and critically described; and the historical aspect of the subject, from the description of rickets by Glisson in 1650 down to the present time, is exhaustively treated. As might be expected, most of the book is taken up by the consideration of rickets. The history of rickets; its geographical distribution; experiments on animals made to elucidate its etiology; and its metabolism, pathology, diagnosis, prognosis, and treatment are dealt with in different chapters. Other chapters are devoted to late rickets, osteomalacia, and infantile tetany.

It is now universally recognized that the antirachitic or calcifying vitamin, or vitamin D, whether present in natural food or prepared by the action of ultra-violet radiations on ergosterol, completely dominates bone calcification. Dr. Hess was associated with Rosenheim, Webster, and Windaus in the important discovery that ergosterol is the parent substance of vitamin D. By this discovery the two apparently unrelated observations—namely, that rickets could be prevented or cured both by the antirachitic vitamin and by sunlight—were brought into complete harmony. Hess, in his book, lays greater stress on the absence of sunlight as an etiological factor in rickets than on the absence of vitamin D from food, and in the past this allocation of responsibility may have been justified. But it would be a sorry look-out for civilized man, especially in this country, if this should hold true now and in the future. With all the good will in the world, even if we were prepared to go about naked, we would find it difficult in England to procure from the sun enough ultra-violet radiations to keep our bones straight and well calcified. It cannot be too much emphasized that rickets can be completely prevented in this and in other countries, independently of sunlight, if sufficient vitamin D is included in the diet from birth, and pre-natally in the mother's diet. It is equally certain, though Hess, as judged by the section on teeth (chapter viii), has not appreciated the fact, that calcification of the teeth is controlled by the same factors as those that calcify the bones. Of course, in comparing teeth and bones it must be remembered that the common defects of the temporary teeth are not usually obvious unless they are looked for with great care; also that the deciduous incisors (the teeth most easily seen in the mouth) are developed in large part during foetal life and lactation, at a time when there is least danger of a vitamin D deficiency. It would appear probable that gross rickets will soon disappear now that our knowledge of its etiology is so advanced, but this achievement will not be sufficient if minor forms of rickets and dental hypoplasia, and, to a large extent, dental caries, are not also banished. If the intake of vitamin D were sufficient throughout growth, including the pre-natal period, not only would all rickets disappear, but the teeth of civilized man would become white, shiny, and evenly arranged like those of the African native living in his natural habitat, and dental caries would be as rare among us as among these people.

Another aspect of rickets etiology which receives only a passing reference in this book is the effect of cereals in producing defective bone formation. It is true that the rickets-producing effect of cereals can be antagonized by an abundant vitamin D intake; but the deficiency of vitamin D in our food would not be such a pressing social problem were it not for the fact that cereals form 60 per cent. of the average English diet. The baneful effect of cereals must be taken into account not only in the etiology of rickets, but in infantile tetany, and especially in osteomalacia, where calcium is actually taken from the bones. Considering the importance that many clinicians have attached to the part played by cereals in the etiology of rickets—to say nothing of the experimental evidence—it might have been expected that more attention would have been given to this point.

The elucidation of the etiology of rickets and its allied disorders is one of the finest instances of international teamwork in medical science; and, for this reason alone, Hess's account of the investigations ought to be read. Like everything "sublime," the position has its "ridiculous" side—although some would probably apply a stronger epithet—in the fact that English people have the privilege of paying a substantial tax to America for making vitamin D by irradiation. Fortunately cod-liver oil is still untaxed. This, however, has nothing to do with Hess's book.

Much could be written about the book, especially in terms of praise, but sufficient has been said to give the reader an idea of its excellence and its limitations. If there is anyone interested in medicine who does not know the difference between "observation" and "experiment and observation" he should read this book; so, too, should anyone who wishes to become a leader in medical science and thinks he can attain this position without becoming familiar with laboratory methods of investigation. Again, anyone who does not know that "what Manchester thinks to-day the rest of the world will think to-morrow," should at least read the part that tells how the Manchester Royal Infirmary, in 1768, used a hogshead of cod-liver oil annually in the treatment of disease. Finally, all those interested in public health and who write so glibly of "preventive" medicine would probably begin to realize, if they read this book, that in vitamin D they have one of the two greatest dietetic weapons at present known—the other is vitamin A—for preventing widespread bodily defect and ill health. They might even be persuaded to advocate its use in preventive medicine and help to rid the country of rickets and defective teeth.

EDWARD MELLANBY.

[1] *Rickets, including Osteomalacia and Tetany.* By Alfred F. Hess, M.D. London: H. Kimpton. 1930. (6 × 9½, pp. xv + 365; 52 figures, 1 plate. 28s net.)

TUBERCULOSIS PROBLEMS.

IN a work of 125 pages[2] Dr. R. KNUD-PEDERSEN has covered a wide field, which includes the reform of tuberculosis statistics, an account of the clinical picture and diagnosis of pulmonary tuberculosis, a denunciation of sanocrysin and all its works, an appreciation of treatment by artificial pneumothorax, a polemical essay on tuberculosis in childhood, an appraisal of the achievement of Papworth Village Settlement almost as eulogistic as an obituary notice, an account of the work of the tuberculosis station in Copenhagen, which the author has directed for the past ten years, and a chapter on "Tuberkulose Kultur"—by which is meant education of the public, beginning with children at school age, in the elements of tuberculosis and the campaign against it. Wide fields are apt to be barren; but in this case the author has so much interesting information to impart, and he infuses it with so much didactic vigour and eloquence, that his work is pregnant with ideas and possibilities. On the principle that "whom the Lord loveth he chasteneth," the author shows his appreciation of the tuberculosis work in his own country chiefly by criticizing it. His complaint is not merely that the whole system of tuberculosis statistics and calculations of the expectation of life of the consumptive is inaccurate and misleading. While, during the last few years, other countries, such as Germany, have effected epoch-making advances in the patho-

[2] *Tuberkulosespørgsmaalene.* Dr. med. R. Knud-Pedersen. Copenhagen: V. Thaning und Appel. 1929. (6 × 9, pp. 125. Kr. 3.50.)

logy and treatment of tuberculosis, Denmark has lagged behind, partly, he suggests, because she has been too much occupied with sanocrysin, on the evils of which he seems to find it difficult to express himself adequately. It would, however, be unjust to Dr. Kjer-Petersen to suggest that his criticisms are mainly destructive; in fact, for every problem discussed in his book he suggests some useful and constructive solution.

In the chapter on artificial pneumothorax the author quotes the following remark made to him by Professor Saugmann, a few days before his death: "We shall make no further advance with pneumothorax treatment before we learn to begin it much earlier." The author then shows how Saugmann's prophecy has been vindicated by the researches of the modern German school led by Assmann and Redeker, whose work on "Frühinfiltrater," and all that this term connotes, has upset the old pathology which saw in apical lesions the beginning of pulmonary tuberculosis. As the author points out, in 80 per cent. of all cases pulmonary tuberculosis in the adult begins, according to this new teaching, as an acute unilateral "Frühinfiltrat"; and if the symptoms associated with this state of affairs do not subside in a couple of weeks an artificial pneumothorax is indicated. So the time may not be far distant when, with the help of x rays, most cases of pulmonary tuberculosis will be detected at a very early stage and the patients will be hustled off to hospital and treated by an artificial pneumothorax next day. Dr. Kjer-Petersen has written a book which might well be studied, not only by the specialist in tuberculosis, but by the practitioner of any other branch of medicine.

THE SURGERY OF CHILDHOOD.

THE surgery of childhood is a subject of growing importance. In France it is considered a specialty in itself, and before very long we in England may have our children's surgeons as we now have children's physicians. In paediatrics America seems to possess much the same outlook as ourselves, and we welcome an authoritative textbook representative of their teaching. Dr. SAMUEL WALTER KELLEY appears to have been first in this particular field, and the third edition of his *Surgical Diseases of Children*[1] has recently been published. It is a work of some importance, and covers the whole subject in two substantial volumes. Their arrangement, printing, and paper are excellent, and the 615 illustrations are well chosen and well produced.

Dr. Kelley has a ripe experience, and is at his best when he mixes the soda of anecdote with the strong waters of wisdom. He seems familiar with every part of the child's disordered system, and admits no specialist preserves on his estate. We had hoped, however, to find in a book of this size something about prognosis in children's diseases. How many umbilical hernias spontaneously disappear? How many bronchiectatics die young? What are the chances of survival with double empyema, and what are the late results of operation for undescended testis? These and a hundred other questions remain unanswered and await an index of prognosis which nobody will be able to write until we have a series of organizations on the lines of the American Commission on Bone Sarcoma. Perhaps it may seem ungenerous to take Dr. Kelley to task for one of the few attempts at prognosis which he does make, but we cannot agree that only 5 per cent. of herniae in children "need operation to effect their cure." The author tells us that he has been laughed at in Europe for advising trusses up to the age of 2 or 3 years, and he attributes this attitude to the bad trusses and indifferent home care which prevail over here. He pleads for removal of the cause as a first step in the treatment of inguinal hernia, and then enumerates the dreary list of "cough, constipation, phimosis, calculus, crying, malnutrition, and emaciation." Surely the presence of a sac is the cause of inguinal hernia, just as the presence of a Meckel's diverticulum may be the cause of acute intestinal obstruction.

Orthopaedic subjects are well described. Fractures and tuberculosis, poliomyelitis, and congenital deformities are fully considered. Cerebral diplegia is particularly well done, and the five pages describing Stöffel's operations on motor nerves give useful practical details. Dr. Kelley speaks very highly of these admirable little operations, but at the same time is careful to emphasize the importance of training and education. Modern surgery has done much for children: perhaps the greatest advances within recent years have been in the treatment of poliomyelitis, cerebral diplegia, and congenital pyloric stenosis. The last-named condition receives due notice, but the author hardly lays sufficient stress on the palpation of the pyloric tumour, which should be the sheet anchor of diagnosis. He considers pyloric stenosis to have two forms—the hypertrophic and the spasmodic; whereas we in England are accustomed to look upon pylorospasm as a separate condition requiring quite different treatment. Dr. Kelley makes it clear that hypertrophic stenosis demands Rammstedt's operation, but he seems to imply that operation may be necessary in pure spasm, and that a tumour is sometimes palpable in that condition.

In a work of this size by one writer there are certain to be some shocks for the reader, and we admit to surprise on several occasions. "English hospitals are too cold" may be true, though we doubt it. Coley's fluid may have an effect on sarcoma, but radium surely deserves mention. "Treatment of osteomyelitis of the spine is by laminectomy," and "most cases" (of tuberculous peritonitis) "terminate in death by exhaustion" leave us unconvinced. Such minor blemishes, however, only serve to emphasize the solid worth of the book as a whole. Weighty and statesmanlike sometimes, but always critical and sane, Dr. Kelley deserves to make many new friends on this side of the Atlantic.

HEREDITY IN MAN.

THE subject of heredity does not, perhaps, throw that glamour upon ardent minds which it cast when those who are now middle-aged were young. To anybody who has read that masterpiece, *The House of the Seven Gables*, seemed to connect the romance of human experience with the methods of exact science, while the work of Galton's greatest pupil, Karl Pearson, on the one hand, and the rediscovery of Mendel's work on the other, opened up paths of research congenial to persons of different psychological types, and both likely to lead to new and fascinating adventures. These hopes have been fulfilled, but the reader of Professor R. RUGGLES GATES's inventory of the objects discerned by the adventurers will probably feel that, although knowledge of particular facts is accumulating with rapidity, the interrelation of these facts is obscure, and that the time when a Newton or a Darwin will be able to give us a comprehensive philosophy of the subject is far beyond the horizon of our generation.

The task Professor Ruggles Gates set himself was this. Having prefaced his work, *Heredity in Man*,[2] with a short but clear sketch of what seems to be the fundamental mechanism of hereditary transmission, he proposed to make a reasoned inventory of the observed facts, and to state the provisional interpretation of these facts, which we owe to modern investigators. He has performed this task with commendable impartiality, and the medical reader in search of a précis of what is known respecting the hereditary transmission of any human character, normal or pathological, will find the book a useful guide. The chapter on blood groups will be particularly valuable, when one remembers the importance this subject has assumed in connexion with modern work on the artificial immunization of the population against various diseases and the interpretation of such reactions as the Schick test.

No doubt a medical reader—particularly if he is interested in psychopathology—may question whether "left-handedness" and "asthma" are sufficiently simple "states" or "diseases" for the summarizing method of

[1] *Surgical Diseases of Children.* By Samuel Walter Kelley, M.D., LL.D., F.A.C.S. In two volumes. Third edition, revised and enlarged. London: H. Kimpton. 1929. (Sup. roy. 8vo; vol. i, pp. xxv + 701, 287 figures; vol. ii, pp. xiv + 663. 65s. net the two volumes.)

[2] *Heredity in Man.* By R. Ruggles Gates, Ph.D., LL.D., F.L.S., F.R.A.I. London: Constable and Co., Ltd. 1929. (5½ × 9, pp. xiii + 365; 87 figures. 24s. net.)

description to be satisfactory. But a perusal of Professor Ruggles Gates's chapter on racial crossing—perhaps the most interesting in the book—will convince even a sceptical reader that the author is well aware of the complexity of the phenomena of inheritance, of the danger of unqualified affirmations. Those politicians who feel moved to predict the advantages (or disadvantages) of racial crossing may be exhorted to read Professor Ruggles Gates's chapter on the subject; if they do so some nonsense will remain unuttered. Professor Gates does not, however, shirk definite statements on racial problems when, in his opinion, the general trend of the evidence authorizes them. He thinks that we may safely hold that the intermixture of unrelated races is eugenically undesirable. "It is possible," he writes, "that crosses between an advanced and a native race may be advantageous as leading to progress in certain tropical regions where the white man cannot survive, although the results of such interbreeding in various tropical countries do not lead to a very hopeful outlook. But the melting-pot conception is being discredited by eugenic writers in the United States, where intercrossing has been taking place on a great scale. It may now be recognized that, while interbreeding of related races or strains may give increased vigour, at least in the F_1 generation, crosses on a large scale between more distant races which have for ages been separately evolving create unnecessary problems, and are, for the most part, wholly undesirable in their results. The more advanced race is diluted and degraded by such intermixture, and primitive mental and moral characters are placed on a level with the more highly evolved."

The book is not easy reading, partly because of the multitude of facts described, partly because the author's literary style is undistinguished; but it is an important contribution to scientific literature.

FLIGHT.

This Bondage: A Study of the "Migration" of Birds, Insects, and Aircraft,[1] by Commander BERNARD ACWORTH, is a charming work that will be welcomed by all his fellow bird lovers for the very clear exposition which it contains of the principles of bird flight. It is also notable for its vigorous prose style and its hearty and seamanlike onslaught on those whom the author regards as his opponents in bird-lore—biologists, palaeontologists, physiologists, anthropologists, pestologists, *et hoc genus omne*, with their speculations and theories of evolution and adaptation. To him all such, with few exceptions, are false prophets, by whom ornithologists have been led into the path of error. Birds, he considers, are animate machines bound by natural law, whose behaviour is to be interpreted on mechanical and physical principles alone, without the necessity of postulating the evolution of mental attributes. This point of view is familiar to students of the history of science, and is generally considered to have been proved to be inadequate when applied to vital phenomena; and with regard to erroneous speculations, there is much truth in von Baer's dictum, that science is better served by a clearly expressed theory, even though erroneous, than by a cautious reserve. It is at least doubtful whether we should ever have had Commander Acworth's delightful little volume had it not been for the alleged erroneous speculations of the ornithologists and other scientists above mentioned. In the final chapters a comparison is drawn between birds and aircraft as regards their efficiency in long-distance flight. Birds are believed to possess a sense of locality which enables them to reach their destination however great the drift from the bee-line may be, provided their strength holds out. Aircraft, on the contrary, when out of sight of land, have no means of ascertaining to what extent they have been carried out of their course by cross-winds. The author does not conceal his opinion that the ultimate results of the present efforts in the development of aircraft are unlikely to justify the appalling expenditure in life and money.

NOTES ON BOOKS.

ONLY a year has passed since the publication of the second edition of Dr. SAMSON WRIGHT'S *Applied Physiology* (reviewed in these columns on June 15th, 1929), but in the interval the work has been thoroughly revised, and the third edition,[2] recently issued, embodies much new material. Of special interest in the present edition is the section on conditioned reflexes; in a dozen pages Dr. Wright provides an epitome of the more important aspects of Pavlov's work and theories that may well serve the student and practitioner as a guide to the intricacies of Pavlov's own writings. Keeping in mind the special needs of two classes of readers—namely, clinicians seeking a sound physiological basis for their work, and students of "pure" physiology—Dr. Wright has indicated in italics in the table of contents and in the synopsis at the head of each section those parts of the subject which are wholly or mainly of clinical interest.

Although it is thirty years since the death of Professor Joseph Coats (1846–1899), who did so much for pathology in Glasgow, many students in the final quarter of the last century will welcome the pious action of his daughters in publishing *Dr. and Mrs. Joseph Coats: A Book of Remembrance*.[3] Mrs. Coats lived on till 1927, and her daughters have naturally much to say about her most charming personality. Coats belonged to the family of J. and R. Coats, the prosperous thread manufacturers, but he had not the advantage, or handicap, whichever form it may take, of wealth, as may be seen from his brief autobiographical notes (or, as he called them, "My book of egotisms") with which the volume begins. In them the reader has the opportunity of gathering from meditations, never intended for publication, the mental attitude of a deeply religious, grave, and thoughtful man of the mid-Victorian era. It is curious that he regarded introspection as one of the worst forms of disease. After some months as assistant to Lister in the Royal Infirmary, and two visits to Germany, where he worked at Leipzig with Ludwig and at Würzburg with von Recklinghausen, Coats settled down in the now rare combination of a throat specialist and a pathologist. Marrying in 1879, he was a candidate for the chair of pathology at Cambridge in 1884, when C. S. Roy was elected, and continued the uphill fight for the recognition of the vital importance of pathology as the pioneer, and for many years the only teacher, of the subject in Glasgow, now the Alma Mater of so many professors of pathology in Great Britain. In 1894, after having lectured for twenty-four years, he became the first professor of pathology in the University, but unfortunately, too soon after the reward of his life's work had come, his health began to fail. This volume contains appreciations from his friends and colleagues and some of his speeches and addresses.

Within a few months of the publication of its predecessor (see *Journal*, November 30th, 1929, p. 1014) the fourth volume[4] —Gelenkerkrankungen (chirurgisch) –Herzkrankheiten—of the new German dictionary of practical medicine, edited by Professors GEORG and FELIX KLEMPERER, has made its appearance. The articles, like those in the previous volume, are the work of well-known authorities, and give an excellent insight into German medicine. The twenty subjects discussed comprise surgical joint diseases by Professor E. Payr of Leipzig, articular rheumatism by Professor A. Schwenkenbecher and Dr. K. Eimer of Marburg, tuberculosis of the bones and joints by Dr. Kotzeborn, industrial diseases by Dr. E. W. Baader of Berlin, gout by Professor O. Minkowski of Wiesbaden, glaucoma by Professor K. Wessely of Munich, gonorrhoea by Professor W. Fuci of Breslau, the medical referee by Dr. Scholtze of Berlin, haematuria and haemoglobinuria by Professor G. Klemperer of Berlin, haemophilia and haemorrhagic diathesis by Professor E. Frank of Breslau, diseases of the throat and larynx by Professor A. Seiffert of Berlin, skin diseases by Dr. A. Joseph of Berlin, tuberculosis of the skin, including lupus, by Dr. Walther Krantz of Cologne, hernia by Professor L. Schönbauer of Vienna, herpes febrilis and herpes zoster by Professor Hetsch of Frankfort, examination of the heart by Professor E. Stadler of Plauen, congenital malformation of the heart and large arteries by Dr. Katz of the Moabit Hospital, Berlin, and Dr. F. Lehr of Bad Nauheim, acquired valvular disease by Professor Pässler of Dresden, and diseases of the myocardium and cardiac nerves by Professor W. H. Weil of Jena.

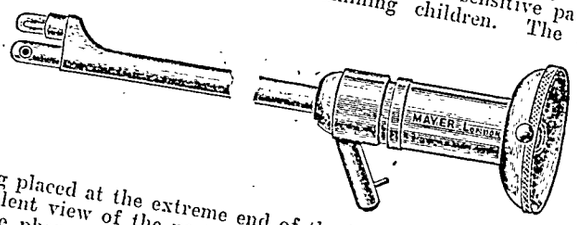
[3] *Dr. and Mrs. Joseph Coats: A Book of Remembrance.* Compiled by their Daughters. Glasgow: Jackson, Wylie and Co. 1929. (Post 8vo, pp. viii + 330; 13 illustrations. 5s. net.)

[4] *Neue Deutsche Klinik.* Herausgegeben von Professor Dr. Georg und Professor Dr. Felix Klemperer. Vierter Band. Berlin and Vienna: Urban und Schwarzenberg. 1930. (Sup. roy. 8vo, pp. 811; 209 figures, 15 plates. Paper cover, R.M.33; bound, R.M.45.)



The appearance of the sixth edition of *Lippincott's Quick Reference Book for Medicine and Surgery*,[2] by Dr. GEORGE E. REHBERGER, two years after the fifth edition is ample proof of the wide popularity of this compendium. The present issue has been brought up to date by substantial changes in about thirty articles.

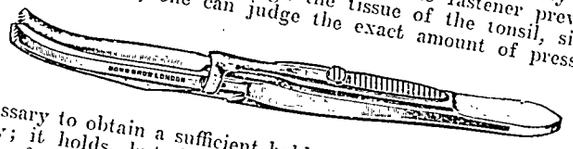
PREPARATIONS AND APPLIANCES.

MODIFIED HAY'S PHARYNGOSCOPE.

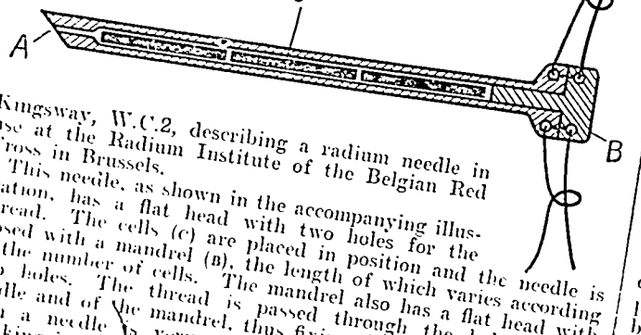
DR. E. E. BURNIER (Margate) writes: This instrument, which has been made to my design by Messrs. Mayer and Phelps, is a modification of Hay's pharyngoscope. It is very much smaller, and consequently better borne by a sensitive patient, and is especially useful in examining children. The lens,



being placed at the extreme end of the instrument, gives a most excellent view of the post-nasal space and of the larynx.

The pharyngoscope should be introduced in the mouth with the light switched on, pressing lightly on the tongue to get under the arch of the soft palate; the patient should be told to close his mouth and breathe through the nose so as to bring the soft palate forward.

A TONSIL-HOLDING FORCEPS.



Dr. A. G. VARIAN (Watford) calls attention to the merits of a new tonsil-holding forceps, here illustrated. He writes: The advantages of the instrument over others I have personally used are as follows: (1) The sliding, detachable fastener prevents the teeth from biting through the tissue of the tonsil, since, by means of it, one can judge the exact amount of pressure

necessary to obtain a sufficient hold. (2) It never slips or tears away; it holds, but does not bite through. (3) It is solidly built of stainless steel, has strength to stand hard work, and can be taken apart for cleaning. I have found it highly satisfactory in every way, and can thoroughly recommend it to those who know the annoyance of most types. It has been made for me, on my instructions, by Down Bros., Ltd.

A SAFETY RADIUM NEEDLE.

Attention was called in the *Journal* of January 4th (p. 29) to the mechanical problems of radium therapy, and, in particular, to the danger arising from the liability to detachment or breakage of radium needles and tubes. In this connexion we have received a letter from the managing director of Watson and Sons (Electro-Iedical), Ltd., of Sunic House, Parker Street, Kingsway, W.C.2, describing a radium needle in use at the Radium Institute of the Belgian Red Cross in Brussels.

This needle, as shown in the accompanying illustration, has a flat head with two holes for the thread. The cells (c) are placed in position and the needle is closed with a mandrel (B), the length of which varies according to the number of cells. The mandrel also has a flat head with two holes. The thread is passed through the holes of the needle and of the mandrel, thus fixing the two firmly together. such a needle is very strong, and the danger of a thread breaking is minimized by two being used. At the point of the needle there is a narrow channel (A) which allows the passage of a very thin mandrel for the expulsion of the radium cells after use.

ETIOLOGY OF DENTAL CARIES.

MRS. MELLANBY'S REPORT ON DENTAL STRUCTURE IN DOGS.

"IT is well known that some people with neglected mouths have teeth free from caries, whereas others who take great care in matters of oral hygiene have extensive caries. In fact, the most rigid adherence to the commonly accepted rules of dental hygiene constitutes no safeguard against a dental disease." This passage, taken from the introduction to *Diet and the Teeth: An Experimental Study*[1] by May Mellanby, expresses in a nutshell the criticism on clinical grounds, of the hitherto generally prevailing view that the production of dental caries depends almost exclusively on conditions external to the teeth. It suggests moreover, that, in looking for the etiology of dental disease the possibility must not be neglected that some constitutional factor might be responsible; in short, that in dental structures there might be a defensive mechanism, in maintaining whose integrity the body as a whole may take some part. A hint as to the direction in which such a defensive mechanism is to be sought appeared in Professor Edward Mellanby's well-known work on the function in the animal economy of vitamin D. This vitamin, Professor Mellanby showed, has a specific controlling effect over the function of bone formation, as much over the development of the jaws as over that of other bony parts. Mrs. Mellanby, following up this point, made the further observation that, not only the formation of the jaws but the architecture of the teeth was directly dependent on the presence at the right time of vitamin D in the diet.

During the twelve years that have elapsed since this observation was made, Mrs. Mellanby, with financial support from the Medical Research Council, the panel practitioners of Sheffield, and the Dental Board of the United Kingdom, has continued her investigation of the etiology of dental disorders, and in the volume issued this week by the Medical Research Council (the first of a series of three) she gives an account of her experimental studies on diet and dental structure in dogs. Her main conclusion is that "the minute structure of the developing tooth and the reaction of the developed tooth to caries are influenced by the chemical nature of dietetic ingredients, which, after being digested and absorbed, are carried into the blood stream to the tissues of the body, and thus to the teeth. They also indicate that the structure of the periodontal tissues is dependent on the chemical nature of the food during the developmental period, and that the diet during this early period is also related to the future onset of periodontal disease."

The Earlier Group of Experiments.

Having, in the earlier chapters of the report, cleared the ground by describing the normal processes of development, eruption, and shedding of the teeth in dogs, and given a detailed account of the methods adopted in her investigation, Mrs. Mellanby sets out the experimental evidence for the conclusion that dietetic factors play a predominant part in determining the character of the teeth and jaws as regards both their general development and their microscopic structure. The first group of experiments concerned the influence on dentition of vitamine associated with fats, and showed in general that calcification was largely dependent on the presence in the diet of a vitamin of somewhat similar distribution and properties to vitamin A. The differences in distribution between this vitamin and the unknown factor favourable to calcification were sufficiently marked, however, to suggest that the two substances were not identical, and the latter, eventually differentiated as a separate entity, is now known as vitamin D, or the calcifying or antirachitic vitamin.

[1] Medical Research Council. Diet and the Teeth: An Experimental Study. Part I. Dental Structure in Dogs. By May Mellanby, M.D. H.M. Stationery Office. 1929. 17s. 6d. net.

When this investigation was started the distinction between vitamins A and D had not yet been established, and Mrs. Mellanby, presenting her account in historical sequence, does not identify the calcification-promoting substance with vitamin D till chapter x, in the earlier chapters referring to it as the "calcifying vitamin" or a "fat-soluble vitamin."

Such a method of presentation has undoubted advantages; the reader watches the facts as they accumulate, and at the appropriate moment sees the conclusions in the process of formation. On the other hand, perhaps some greater clarity might have been gained if, in the course of the narrative, earlier experiments had been consistently interpreted in the light of more recent discoveries.

Influence of Vitamin D.

The development of perfect teeth, it was found, could be ensured by giving an adequate supply of vitamin D, either as it appears in natural foods—for example, egg-yolk, milk, suet, and cod-liver oil—or as it may be artificially produced, by irradiating the ergosterol content of food, or by irradiating the animals' skins. In the presence of this vitamin it was difficult to choose a diet so low in its calcium and phosphorus content, or otherwise so unfavourable to calcification, as to interfere materially with the normal development of the dental tissues. On the other hand, it was easy to choose a diet deficient in vitamin D, for the foods containing this substance are few in number and, in general, expensive. It would seem to follow—if the factors controlling the dentition of the dog and the human subject are the same—that the ordinary diet of the poorer classes in this country, which consists in the main of bread, oatmeal, barley, sugar, fruits, jam, vegetables, lean meat, and white fish—all of them vitamin D deficient substances—will tend to produce imperfect teeth.

Other Food Constituents.

Proteins, carbohydrates, most vegetable fats, and foods such as cereals, oranges, and egg-white, gave no evidence of calcifying power. Bacon fat appeared to have but little effect, and hydrogenated animal fats none at all. An increase in the cereal intake had a deleterious effect on calcification, apart altogether from its effect on the rate of growth. Of the cereals tested, oatmeal had the greatest decalcifying power, and white flour the least; intermediate between these were maize (next to oatmeal), then barley, rye, wholemeal flour, and rice. Wheat and maize germs also had an unfavourable effect on calcification. In every case, however, the influence of cereals could be entirely overcome by including in the diet a sufficiency of vitamin D.

It was not found possible to ascribe the anti-calcifying effect of cereals to any one known constituent, such as (*a*) the absolute or relative amounts of calcium and phosphorus, or (*b*) the carbohydrate, fat, or protein, or (*c*) the acid-base ratio of the mineral substances. The evidence suggested that cereals contain an anti-calcifying factor ("toxamin") of unknown composition, which actively interferes with the normal development of the teeth. This unknown substance is destroyed by boiling with dilute hydrochloric acid, and, to a less extent, by boiling with alkalis; it may also be destroyed or antagonized in the process of malting. When present in the grain it is stable to fairly high temperatures, and it resists digestion with diastase and, partially, with trypsin.

Calcium and Phosphorus.

For the production of perfect teeth the diet must naturally contain some calcium and phosphorus, though only small quantities of these are required if the diet is rich in vitamin D. If the vitamin D intake is very low extra calcium may have some beneficial effect, but in the complete absence of vitamin D perfect calcification will not occur, however much calcium and phosphorus is given in the diet.

Maternal Feeding.

Proper maternal feeding on the lines indicated is of great importance in the production of good teeth in the developing offspring. Poorly calcified deciduous teeth were produced in the offspring by feeding the mother on a diet deficient in vitamin D. The defects so produced were, however, less marked than those found in the permanent teeth when the puppy itself was fed on the same diet. It seems probable that, under certain conditions, stored vitamins may be drawn upon, the maternal organism sacrificing to the embryo the factors essential for its normal development and calcification, even though she herself suffers through doing so. The character of the defects in the deciduous teeth probably depends on the amount of vitamin stored in the mother's tissues before pregnancy and the amount present in her diet during pregnancy and lactation. The maternal feeding was found to affect also the future structure of the permanent teeth, for when the mother's diet contained abundant vitamin D, and the offspring, after weaning, were fed on a diet deficient in this substance, the permanent teeth, though defective in structure, were not nearly so defective as those of puppies whose mothers' diet had also been deficient in this vitamin. In short, a deficiency in the mother's diet during pregnancy may influence the offspring throughout its life. Further evidence of vitamin storage was afforded by the fact that when the diet of a puppy was changed from one rich in vitamin D to one deficient in this substance, decalcification did not occur at once, and defective formation of the dental structures appeared after a comparatively long interval.

Effect of Irradiation.

Though vitamin D has such a limited distribution it can be produced by ultra-violet irradiation of foods containing the pro-vitamin ergosterol. Thus, olive oil and peanut oil, though ordinarily without effect on the teeth, became powerful calcifying agents after irradiation. The activity of milk and butter was greatly enhanced by irradiation, and substances which normally interfered with calcification—for example, oatmeal and flour—by this means were made to assist the process. The application of ultra-violet radiations to the skin was not nearly so effective in promoting calcification as a diet rich in vitamin D. Exposure of dogs to sunlight, though beneficial to calcification of the teeth in certain conditions, proved in some of the cases to be practically ineffective when the diet was markedly anticalcifying.

ROYAL MEDICAL BENEVOLENT FUND.

AT the last meetings of the committee of the Royal Medical Benevolent Fund the following sums were voted: December £1,342. January. £1,037—making a total of £2,379; no fewer than 113 necessitous medical men, their widows, or families being helped thereby.

During the winter months the number of applicants is inevitably large; for some the occasion is illness or the lack of ordinary comforts, but for most it is the death of a husband or father who has been unable to make provision for wife or family. The committee urgently appeals for subscriptions, donations, and legacies. Cheques should be forwarded to the Honorary Treasurer, Royal Medical Benevolent Fund, 11, Chandos Street, Cavendish Square, London, W.1.

The following are particulars of five cases recently helped.

Widow, aged 50, of L.R.C.P. and S., whose husband died suddenly in September, 1929, at the age of 51, from heart failure. The widow, who is in very delicate health, was left an income of £50 per annum with children dependent on her. Voted grant of £26 and a special gift of £14.

M.D., aged 60, married, suffering from tuberculosis and in a sanatorium. Practice has been sold, and when proceeds are invested will give an income of £135. Applicant has one son and two daughters; the two eldest have secured posts. Voted £40.

Widow, aged 60, of M.R.C.S., L.R.C.P. Her husband suffered ill health all his life, and was never able to work sufficiently to save any money. At his death in November the widow and one daughter were left with a capital of £200. The daughter fortunately has been trained and will obtain employment. Voted £26 and special gift of £10.

Two daughters, aged 61 and 52, of L.F.P.S., whose only income is £17 each, gifts from friends, and deposit interest on the sum of £57. Voted £36 each.

Daughter, aged 70, of M.R.C.S. Has been in bed during the whole of the last twelve months. Income from charities £30, old age pension £26. Voted £30.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing, especially for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles. The gifts should be sent to the Secretary of the Guild, 53, Great Marlborough Street, W.1.

British Medical Journal.

SATURDAY, FEBRUARY 15TH, 1930.

MATERNAL MORTALITY.

In recent years few medical problems have caused more anxiety to both the profession and the general public than those connected with the dangers of childbirth. While the maternal death rate alone is serious enough to excite alarm, there is also a vast amount of ill health, and therefore of impaired maternal care of children, resulting from the injuries and infections of difficult labour. It is impossible to measure these disabilities, but anyone who has managed a gynaecological out-patient department knows how widely spread is the invalidism directly traceable to childbirth. In a general survey of the problem perhaps nothing is more striking than the fact that, in spite of all that has been done since the war by ante-natal clinics, increased training of nurses, and wider diffusion of knowledge, the mortality associated with childbirth has not declined. Indeed, the figure for 1928—4.42 per 1,000 births registered—is actually higher than that for any year since 1900. An analysis of these figures shows an even more extraordinary state of affairs. The mortality from sepsis in 1928 (1.79) was the highest since 1905, with the single exception of 1920; and from toxaemia the mortality was higher than during the previous seven years, in spite of the widespread practice of urine testing in hundreds of ante-natal clinics and private consulting rooms.

The difficulties of the problem are apparent the moment an attempt is made to find a solution. Attention is first arrested by the number of persons and institutions concerned with the care and treatment of the child-bearing woman. In the complexity of the present-day system we have the general practitioner, the obstetric specialist, the midwife, the local authority through its ante-natal clinics, the health visitor, and the maternity hospital. Confusion is created by divergent views and varied teaching presented in scores of papers, reports, memorandums, and contributions to our correspondence pages. Some feel that the system of domiciliary midwifery is wrong; others that nursing homes and hospitals are apt to increase the risk of contact infections. More State supervision, better training of student and midwife, increased facilities for research, wider use of ante-natal care—all these and many other expedients are put forward in the hope of improving the results of midwifery practice. Examples of contributions to the solution of the problem are three instructive and illuminating papers—by Dame Louise McIlroy, Dr. Gilbert Strachan, and Dr. W. H. F. Oxley—published in our present issue.

In her paper Professor McIlroy discusses, among other matters, the chief causes of death—namely, sepsis, haemorrhage and shock, and toxaemia—and, by referring to the practice in her own unit at the Royal Free Hospital, shows how the application of rigid principles and strict technique can reduce the mortality rate, not indeed to zero, but to a figure substantially less than that for the whole country. Professor McIlroy's hospital figures are in sharp contrast with those published in the Scottish report of Dr. Parlane Kinloch,[1] in which he stated that the maternal death rate in institutions in the Aberdeen area was 14.9 during 1928. It is clear that the maternity institution is not a solution of the problem, but, while some variation exists, it is certainly true that the results obtained in a well-run hospital department lend considerable support to the demand for more obstetric beds. Professor McIlroy says, "some day gynaecological beds will decrease as maternity beds increase."

Similar experiences are related by Dr. Oxley from the East End Maternity Hospital. Here the in-patient death rate since 1884 has amounted to only 2.10 per 1,000, while the "district" deliveries show the astonishingly low mortality figure of 0.74 per 1,000 in over 27,000 confinements. It is the last figure that is particularly worthy of notice, for the experience it represents is common at other maternity hospitals. In several large district services some years have recently passed without a single maternal death; indeed, it is probable that over a period of years no other system of midwifery service could show results in any way comparable to those obtained on the hospital "districts," even in quite poor housing conditions. It is no effective criticism to say that the dying patients are sent into hospital, thereby saving the statistics, for the death rate of the in-patients at Dr. Oxley's hospital, and at others, is still only half that for the whole country, in spite of the fact that dangerous abnormalities tend to become segregated in institutions. Both Dr. Oxley and Dr. Strachan lay stress on the great prophylactic value of ante-natal care, and the former attributes the excellent results of his hospital largely to thorough ante-natal attention.

In the long run good midwifery must rest upon prophylactic care and the conduct of labour itself with cleanliness, patience, and skill; the individual responsible for the one should be responsible also for the other, and must, in general, be the private practitioner. It is widely felt that the staffing of ante-natal clinics by whole-time, mostly junior, officers, who never see the ensuing labour, is fundamentally wrong. In the ideal system the patient would be under the care of the same doctor from the beginning of her pregnancy to the end of the puerperium, and within this system there would be the closest co-operation between the doctor and the midwife. The purely ante-natal specialist, divorced from experience of labour, cannot play any useful or permanent part in the national service. Nor, we may suggest, can the independent ante-natal clinic. As far as possible every ante-natal centre or system of ante-natal care should be definitely associated with a neighbouring maternity hospital, or with the maternity department of a general hospital, whose specialist services should be available in all cases of doubt, both before labour and at the confinement itself. Doctors and midwives should feel that the maternity hospital is behind them and forms part of the scheme. In many rural districts it is obvious that distance might give rise to difficulties, but transport improvements are rapidly overcoming the isolation of village communities, and increasing the contact between the local town and outlying areas. Even so, as Dr. Oxley says, "the general practitioner may have to take over a large part of the examinations now being done by the ante-natal clinics, leaving to them the work which they can most usefully do, such as the teaching of mothercraft."

[1] See *British Medical Journal*, January 12th, 1929, p. 79, and January 19th, 1929, p. 115.

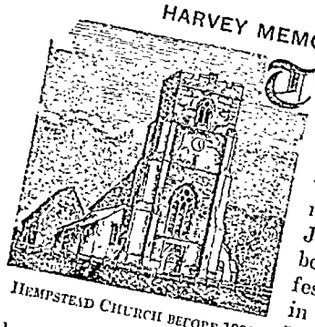
No solution of the problem of maternal mortality can be complete that fails to take account of the training of the midwife and the doctor. The difficulties of this latter problem are strikingly emphasized by Mr. Comyns Berkeley in his Lloyd Roberts Memorial Lecture on the teaching of midwifery, published in the current number of the *Journal of Obstetrics and Gynaecology of the British Empire*. Two main facts emerge from his investigation of the system of teaching: there is a paucity of what is called clinical material available for teaching, and some educational and hospital-school authorities are failing to offer the student sufficient time and opportunity for him to acquire a thorough practical knowledge of midwifery. Until the authorities concerned get down to these fundamental weaknesses in training it seems certain that we shall continue to deplore the high rate of death and disablement in childbirth.

EPIDEMIC ENCEPHALITIS AND ITS LITERATURE.

If for a moment we allow ourselves to fancy, with certain of the ancients, that the manifestations of disease are due to the workings of devils who take possession of human bodies, then we might imagine that the devil responsible for encephalitis lethargica, or epidemic encephalitis, feels flattered at the amount of attention he has attracted. He would recall the mystery surrounding his first appearance on this earth, and the efforts made by several countries to claim him as a national; he might acknowledge that his attempt to masquerade in England as the Botulinus imp was quickly exposed, but he would chuckle over the clinical confusion which for some time he created, and at the various descriptions given of him as he appeared now in this country, now in that. The failure of all medicinal measures to exorcise him, and the anxieties and difficulties he causes those concerned with the care of the many victims from whom he never departs, are no doubt a source of grim satisfaction. But this comparatively modern devil probably derives most enjoyment from the fact that more has been written about himself than about any of his contemporaries.

The literature of epidemic encephalitis, indeed, shows signs of reaching almost overwhelming proportions, and it has occurred to a liberal-minded American that the time has come to overhaul and analyse this heap of literary material, so that it can be the more easily probed by those in search of information on any particular point. Accordingly a team of ten American investigators, known as the Matheson Commission (*in honour of the promoter, Mr. W. J. Matheson*), and with Dr. Josephine B. Neal as director, was appointed for the purpose about three years ago, and has recently issued a report of its survey.[1] Primarily the commission busied itself with a library study of the world's literature on the subject of epidemic encephalitis, but its members visited various parts of America, as well as England, France, Holland, and Belgium, for the purpose of interviewing physicians and others interested in the subject. The 4,643 references which have been collected and set out in the report occupy 428 pages, or just over half the total volume of the book. This bibliography, in itself, emulates the character but exceeds the scope of two or three notable predecessors in our own country; the new and more valuable feature of this survey of literature, however, is provided by the abstracts which have been made from the various reports and articles dealing with three aspects of the disease—namely, etiology, treatment, and epidemiology. The chief points in the story of the efforts to discover the cause and nature of the infection are judicially set out, and the reader is left to draw his own conclusions. Most, however, will agree with the commission's single comment that "in spite of the vast amount of experimental work that has been done, there are still widely varying opinions in regard to the etiology of epidemic encephalitis." The balance of evidence seems to point to the hypothesis that a filterable virus closely allied to the herpes virus is the specific agent. The more recent literature concerning other types of encephalitis, including post-vaccinal encephalitis, is briefly surveyed. It is suggested by the reviewers that, in the case of post-vaccinal encephalitis, the age limit is far wider than is usually stated, that a purely clinical distinction between encephalitis lethargica and post-vaccinal encephalitis is often difficult, if not impossible, and that "the study of a larger group of cases [of post-vaccinal encephalitis] revealed residuals in a number of instances."

The list of remedies which have been tried, as revealed by the summary of the literature, is extraordinarily varied: apart from a large number of drugs, it includes such measures as the use of vaccines and serums, blood transfusion, injection of foreign proteins and the organisms of malaria and recurrent fever, organotherapy, psychotherapy, and various forms of physiotherapy. Many of these remedies are apparently "shots in the dark." The few useful remedies include atropine, hyoscine, bulbocarpine, and stramonium, but reports show that even these drugs have only a limited use in the symptomatic treatment of certain chronic cases; it is no surprise to find that the survey has not discovered evidence pointing to any specific remedy for this form of encephalitis.



In their analysis of the literature pertaining to the epidemiological side of the disease, the authors have realized that it is impossible to measure at all accurately from official records the total incidence of encephalitis lethargica throughout the world. For one thing, the disease is by no means universally notifiable, either throughout the countries as a whole or even in all parts of a country from which cases are officially reported; again, in certain countries deaths only are reported. In other instances there is a certain amount of obscurity about the nature of reported cases such as exists with regard to the Australian "x disease" of 1917–18 and the extensive Japanese epidemic of encephalitis in 1924. The League of Nations, however, through its monthly *Epidemiological Reports*, has evidently been of considerable service to the commission. The fairly reliable returns—for example, from England and Wales, Sweden, Finland, Denmark, Switzerland, and Italy—show that from these countries collectively there were 31,995 cases reported during the period 1920 to the end of June, 1928, the peak years being 1920 and 1924. Encephalitis lethargica is, in general, more prevalent during the winter months, but the League's epidemiological report for February, 1927, stated that "the disease . . . during the last two years has shown a tendency towards attaining an endemic level subject to moderate seasonal fluctuations." From the histories of 9,680 cases derived from the general literature the commission tabulates certain other findings. The sex incidence seems to be greater upon the males (58.7 as against 41.2), and the greatest proportion of

[1] Epidemic Encephalitis: Etiology, Epidemiology, Treatment. Report of a Survey by the Matheson Commission. New York: Columbia University Press. 1929.

cases—25.3 per cent.—occurs during the age period 20 to 29; the present more comprehensive survey confirms the conclusions reached in this country that neither occupation nor sanitary circumstances have any direct bearing on the occurrence of cases. As regards mortality, it is recorded that of 7,876 cases collected from the literature, 3,980 were reported as fatal; this gives a fatality rate of 50.52 per cent., but due allowance must be given to the fact that very few mild cases of encephalitis lethargica find their way into the general literature, even when they are recognized.

The Matheson Commission has successfully accomplished the task for which it was formed, and the hard labour involved in an undertaking of this sort will doubtless be rewarded by the gratitude of those who will find in this first report an unusually comprehensive and handy book of reference.

HARVEY MEMORIAL AT HEMPSTEAD.

HEMPSTEAD CHURCH BEFORE 1882.

THE appeal, of which a preliminary announcement was made in our issue of December 7th, 1929 (p. 1072), and to which Sir John Rose Bradford referred in a note published on January 4th (p. 25), has now been issued to the medical profession. William Harvey died in his eightieth year, on June 3rd, 1657, and his remains were deposited in a vault adjoining the parish church of Hempstead in Essex. By the middle of the last century this vault underneath the Harvey Chapel had become ruinous. On January 28th, 1882, the massive tower of the church fell towards the south-west; it is still a heap of stones in the churchyard. In 1883 the mortal remains of the founder of scientific medicine were removed from the vault and placed in a handsome marble sarcophagus, erected by the Royal College of Physicians of London, in the chapel above the vault, which also contains memorials to other members of the Harvey family who achieved distinction. Some years ago a committee was formed for the purpose of restoring the fallen church tower as a further memorial to William Harvey. About £1,000 was raised, in part locally and in part from the medical profession. The committee has now been reconstituted, and its appeal is addressed to the medical profession of the British Empire in the hope that the sum required to restore the tower (about £5,700 in all) may be obtained with as little delay as possible. The village of Hempstead lies in a sparsely populated district seven miles from the railway station of Saffron Walden, and some fifty from London. Local resources are wholly inadequate for carrying out this pious project. Thus the medical profession has the opportunity of providing, in the words of the President of the Royal College of Physicians, "a suitable memorial of a striking character to one of the greatest of men. . . . It may be that in years to come the tower of this ancient church of Hempstead, in Essex, will be known as the Harvey Tower, and this tower will not only commemorate Harvey and his work, but it will also be a token of the esteem and admiration with which Harvey's work is regarded by those best qualified to judge its real value." Donations should be made payable to the Harvey Memorial Fund, and may be sent to the joint honorary secretary, Dr. Arnold Stott, 58, Harley Street, W.1, who will gladly supply printed copies of the appeal to any reader who is willing to circulate them among possible subscribers.

THE B.C.G. CONTROVERSY.

AT a meeting of the Académie de Médecine in Paris on January 14th, at which Sir Almroth Wright, foreign associate of the Académie, was present, Professor Calmette presented a further communication on preventive vaccination against tuberculosis by means of the B.C.G. (*Bacillus Colmette-Guérin*). A special laboratory for the preparation of the vaccine has been installed at the Institut Pasteur in Paris, and supplies of the vaccine are sent out for a daily average of 300 infants. Professor Calmette claims that in no case has any accident been shown to be attributable to the vaccine, and that, while acid-resisting bacilli have been recovered from lymphatic glands in necropsies on vaccinated infants who have died of other diseases, tuberculous lesions have never been found, and inoculation of guinea-pigs has always proved negative. In deference to the criticisms of Professor Major Greenwood, Professor Calmette now bases his statistics on a comparison with the general mortality from all causes in infants under the age of 1 or 2 years, and finds that the statistics confirm his conclusion that infants vaccinated with the B.C.G. show greater resistance to infantile diseases and have a lower mortality than the non-vaccinated. He quotes returns from various districts showing the difference in the death rate of as much as 50 per cent., and notes especially returns from two mining districts, Béthune and Liévin, where the majority of infants born were vaccinated with B.C.G. Professor Calmette's statistics still seem somewhat sketchy, and he does not appear to have laid before the Académie the full returns for all the districts where the vaccine is used. Moreover, it is still possible to suggest that some part of the reduced mortality among the vaccinated infants may have been due to the fact that these have been better looked after by anxious parents, watchful nurses, and interested observers, who recorded the results, than the general unvaccinated infant population.

THE LIMITS OF SANOCRYSIN TREATMENT IN PULMONARY TUBERCULOSIS.

WHEN Professor Holger Moellgaard, more than five years ago, suggested that sanocrysin might prove to be beneficial in the treatment of tuberculosis, he based his belief on experimental investigations of the effect produced by injecting this gold preparation into tuberculous animals. In a subsequent article in the *British Medical Journal* (1925, vol. i, p. 643) he pointed out that the extent and gravity of the tuberculous process set a limit to the probable success of this treatment, and he defined the limit as regards calves and goats as being not greater than a weight of 7 cg. tubercle bacilli culture per 100 kg. body weight. He added that the presence of a mixed infection had been shown similarly to militate seriously against the efficacy of sanocrysin. Dr. J. Gravesen, who has succeeded Professor Saugman at Vejlefjord Sanatorium in Denmark, recently called attention to this proviso of Moellgaard, which has not always been kept in mind. One very important claim has survived the controversy which has since raged over the value of sanocrysin; Moellgaard certainly did show that animals exposed to a recent and moderate infection by tubercle bacilli recovered under treatment with sanocrysin, whereas the controls died. Gravesen accordingly, in his employment of this treatment, has endeavoured to select patients who corresponded as closely as possible with Moellgaard's experimental animals, inasmuch as the disease was recent and spreading, and in an article in the *Ugeskrift for Laeger* of December 12th, 1929, he reviews the results of sanocrysin treatment on these lines at his sanatorium between February, 1924, and May, 1929. Gravesen points out first the significant facts that, among the 270 patients whose treatment with sanocrysin was completed in this period, only 26 (less than 10 per cent.) com-

formed to this requirement, and that the results achieved in these 26 cases were remarkably uniform. The treatment was well tolerated in every case, complications playing a much less important part than in the remainder of the patients. In each of these 26 patients striking clinical improvement immediately followed the treatment, accompanied by a corresponding decrease of the stethoscopic and the *x*-ray signs. All the *x*-ray signs of an active spread of the disease disappeared completely in every case, and all the 18 patients who were sputum-positive before or during the treatment became sputum-negative after it. The permanent results were as good as the immediate results, and though the greatest care was taken to follow up these 26 patients in the five-year period under review, not a single case of relapse or reappearance of tubercle bacilli in the sputum could be found. The remainder of the cases treated represented at the one extreme an actively progressive stage of the disease, with comparatively little fibrosis or cavity formation, and at the other extreme a minimum of recent activity and a maximum of chronic changes. The measure of the success of sanocrysin treatment was that of the recent extension of the disease and of the slightness of chronic stationary disease. Gravesen determined, therefore, that he would hardly ever give sanocrysin in chronic "tertiary" forms of the disease unless there was evidence of recent extensions of it. In mixed forms, however, when chronic disease is associated with recent extensions, he combines sanocrysin with collapse therapy, and has found that this combination is more effective than either of these two treatments alone. He usually administers sanocrysin in two courses. The initial dose of the first course is 0.10, 0.25, or 0.35 gram, the doses rising to 0.50, 0.60, 0.75 to 0.85, and up to 1 gram in heavy patients whose tolerance proves satisfactory. The number of days between each injection is calculated according to the dosage of the last injection, four free days being allowed after a dose of 0.35 gram and eight free days after a dose of 0.75 gram. From 5 to 6 grams were given during the first course of injections. After an interval of a couple of months the second course was started, with the same spacing of the injections but with a higher initial dose and a more rapid increase of the dosage; a total of 3 to 5 grams was given. various complications were observed, but only in 2 of the 270 cases did the treatment prove fatal. Gravesen publishes in his report two elaborate tables showing the immediate and late results of this treatment; in properly selected human material these coincided with those observed by Moeilgaard in his experimental work on animals.

A SON ON HIS FATHER.

In a forgotten play by H. D. Traill one of the characters says:

> "Remember what our old friend Flaccus says,
> 'Mighty men lived ere Agamemnon's days,
> Forgotten now, thro' having,' he continues,
> 'No bard to celebrate their thews and sinews.'"

To which the cynic answers:

> "The march of science
> Has taught us to set that fate at defiance,
> For fear no bard should be an aftercomer,
> Each Agamemnon now is his own Homer."

This generalization is too sweeping, even when applied to the species Miles Gloriosus, and still less is it applicable to the mighty dead of medicine. Therefore has it been left to the filial piety of the son to put on record some of the sayings and doings of a distinguished father, whose reputation has been eclipsed by that of the offspring whom he trained, and who owe and acknowledge some of their debt to the founder of St. Mary's Hospital at Rochester, Minnesota. In the *Proceedings of the Staff Meetings of the Mayo Clinic* (December 4th, 1929) Dr. W. J. Mayo tells how "in my father's time" diagnosis and treatment were conducted at Rochester. England claims William Worrell Mayo for her son, for he had his birth and breeding and professional education in Lancashire, as we noted in an annotation in our issue of February 16th, 1929. America gave him that free scope for his abilities which enabled him and his sons to make of a little country town, remote from the great lines of rail and far from great cities, a surgical Mecca to which patients come on pilgrimage from afar, seeking cure with more justifiable hope than the holy wells of Europe can offer to their devotees. Dr. Mayo does not exactly define the "time" in question, but from internal evidence we are led to suppose that it was before the development of abdominal surgery, which was marked by the publication of Sir Frederick Treves's book in the eighties of the last century, for the operative surgery described in this article is scarcely more than minor surgery, restricted to the opening of abscesses, the palliative relief of intestinal and urinary obstruction, the closure of fistulæ, and the removal of small superficial tumours and skin growths. (No doubt the ordinary operations of what was then major surgery—amputations and excisions, etc.—were performed in the classical manner of the works on surgical operations.) The methods described were simple, and in some cases original, and some practical hints which may lead to the greater comfort of the patient may be gleaned from a study of this paper. The sketch drawn is a pleasing one. Its few but clear strokes give the impression of a man of resource and sound common sense, who had profited by experience, "by industry achieved and perfected by the swift course of time." Ripe wisdom is shown in his dictum that if the physician really knew from three to five things of importance about the condition of the patient he probably was a good diagnostician for the case, but that if he thought he knew many things he was probably doing some guessing. We are reminded by the son's descriptions of some of his father's methods of the curious tendency of surgical fashion to abandon some useful proceedings, which become obsolete. Such are the method of treating troublesome moles by transfixion with needles and ligature, or warts with nitrate of mercury. Dr. W. J. Mayo tells us that he still uses the latter, and that he has never known an infection to follow its use.

CARDIAC EFFICIENCY OF YOUNG MALE ADULTS.

THE fact that, eleven years after the conclusion of the war, 16,000 ex-service men are receiving pensions on account of functional heart disease was cited by Wing Commander H. A. Treadgold, R.A.F., in a paper which he read before the United Services Section of the Royal Society of Medicine on February 10th, as affording ample justification for laying stress on the importance of a careful scrutiny of the cardio-vascular system as a whole prior to entrance into the services. The problem, he said, was not merely the elimination of organic heart disease, but the equally important question whether the heart was likely to withstand the acute physical and mental stress inseparable from modern war. Wing Commander Treadgold discussed first certain points of value in routine clinical examination: inspection, palpation, percussion, and auscultation. Percussion might be of value, he said, in determining the size of the heart in a thin individual, but it was at best an unreliable and misleading sign in well-covered or emphysematous patients. An apex beat definitely seen and felt internal to the nipple line in the fifth space in an otherwise normal chest was far stronger evidence of the probable absence of cardiac enlargement than a problematical dullness to the right border of the sternum was of its presence. When the apex beat could be neither seen nor felt recourse to *x* rays was essential before enlargement was definitely negatived. The orthodiagraph was of the greatest value in this connexion. He showed some typical orthodiagraphs, including one of Carnera, the Italian giant boxer, who submitted himself

willingly for examination, and who was found, notwithstanding his immense weight and height and bulk of heart, to be perfectly fit. The stethoscope was the best means of studying alterations in rhythm. Extra-systoles were evidence of irritability in the myocardium, and when they disappeared on exercise, as they usually did, they could be safely disregarded in an otherwise normal heart, but if exercise increased them they should be looked upon with suspicion, especially if auricular. The only method of satisfactorily diagnosing a doubtful arrhythmia was by the electro-cardiogram. Turning to heart sounds, Wing Commander Treadgold said that a reduplicated first sound could be distinguished at the apex in well over 50 per cent. of young adult hearts. Widening of reduplicated sounds after exercise, especially when associated with a poor quality first sound, a tick-tack rhythm, an increased pulmonary second sound, or a triple rhythm at the apex, was suggestive of myocardial mischief. One of the most difficult problems was the differentiation between a reduplicated first sound at the apex and the presystolic murmur of a suspected mitral stenosis, and he instanced a number of points of value in distinguishing the conditions. There was little doubt that in the past undue importance had often been attached to apical systolic murmurs, and there must be a large number of perfectly normal individuals who had been diagnosed as having valvular disease of the heart, whereas in fact there was nothing whatever the matter. A soft apical systolic murmur accompanying the first sound, and varying with position or respiration, in an otherwise normal heart, was of slight or no significance. Turning to the estimation of the degree of stability of the cardio-vascular system, he spoke of the pulse response test, remarking that the average pulse rate of officers selected for permanent commissions in the Royal Air Force, as a result of their flying efficiency, was rarely above 72, and usually below, and practically all the well-known civil pilots had varying degrees of bradycardia, usually about 60 per minute. As for blood pressure, that of a healthy adult under 40 varied as a rule between 110 and 140 systolic and 65 and 85 diastolic. The pulse pressure—the difference between the two—varied between 40 and 50. Small pulse pressures, in the normal individual, even down to 25 mm., were a most valuable sign of cardio-vascular stability, and were usually associated with a slow pulse. It had been found at the Central Medical Establishment that rotation in a chair ten times in twenty seconds, the blood pressure being taken immediately before and after, revealed the fact that the stable individual's blood pressure did not change materially, that faintness and nausea accompanied a fall in an already low diastolic, and giddiness a rise in a high diastolic. An increased pulse pressure of over 10 mm. was unsatisfactory. Wing Commander Treadgold concluded by saying that the characteristics of a stable cardio-vascular system were a slow pulse, with a relatively slight increase on exertion, frequently a bradycardia, and a small pulse pressure, which again tended to remain relatively constant on exertion. In some remarks at the close of the paper Dr. Strickland Goodall said that he was glad that the author had tried to assess the efficiency of the vasomotor mechanism as well as that of the heart, for in connexion with flying it had always seemed to him that the vasomotor mechanism was perhaps even more important. He expressed surprise at the statement that 50 per cent. of young adults had a reduplicated first sound at the apex; this certainly did not hold good for the very large number of young people who passed through his hands in connexion with one of the big industries. Fleet Surgeon Home, with reference to the Royal Air Force tests, quoted an apposite passage written by Boerhaave in 1747: "They who buy slaves count their pulse and respirations in a given time, and then order them to run. If now they find the respiration and pulse not much altered by that violent motion, they know that they are of strong habit of body."

YELLOW FEVER ON THE GOLD COAST.

THE serious outbreak of yellow fever in West Africa in 1927 brought home to the British and French authorities the advisability of some form of co-operation in their endeavours to check the disease. Outbreaks had occurred in the past and were likely to occur in the future; and unless, when a case appeared in any one colony, the various colonies concerned were informed at the earliest possible moment, the necessary precautions could not be taken till the most favourable opportunity had passed. With a view to discussing the best method of procedure, a conference between delegates from the French and British colonies was held at Dakar, at the invitation of the Governor General of French West Africa, and the report of the proceedings by Dr. P. S. Selwyn-Clarke, the delegate from the Gold Coast, which, with Senegal, was most seriously afflicted by the epidemic, forms very interesting and instructive reading.[1] During 1927, from May to December, there were 190 cases of yellow fever in Senegal, with 135 deaths. It is noteworthy that none of these cases was in a native, whereas in the Gold Coast for the whole year there were 107 cases, of which 88 were in Africans. Of the Africans 25 died, and 15 of the 19 Europeans or Syrians. The discrepancy between the native incidence in Senegal and in the Gold Coast is not explained, but it seems hardly conceivable that the native of Senegal is entirely immune. It is significant that during the year the mortality among natives increased, but this is attributed to plague followed by a severe outbreak of malaria. Whatever may be the explanation, the discovery that the native may contract yellow fever in a mild form is of the utmost importance, and is the first step towards the discovery of the reservoir of infection. The fact is in accord with the recommendation that the European should be segregated and placed as far away as possible from the native population. One of the greatest difficulties has always been the early diagnosis of the disease, which does not exhibit its characteristic features till some days have elapsed. During the whole of this initial period mosquitos may infect themselves from the case. The necessity, therefore, of screening any suspicious case from these insects was duly emphasized at the conference. In a febrile disease which was not malaria or other easily recognizable condition, the occurrence in the urine of albumin in increasing quantities was regarded as a diagnostic sign of great importance. Great help in the diagnosis of atypical cases was hoped for from the discovery made by the Rockefeller Commission that the oriental monkey *Macacus rhesus* was very susceptible to the disease. It has been shown that in blood removed from a case during the early stages of yellow fever the virus will survive for relatively long periods, so that the collection of blood for inoculation into susceptible monkeys becomes a practical procedure for diagnosis. As regards treatment, the report admits that there is no known remedy; the use of vaccines should, it is suggested, be optional, since, though innocuous, they have given contradictory results. A resolution was adopted expressing the view that it would be desirable to hold similar conferences for the discussion not only of yellow fever, but of other epidemic diseases. It was suggested further that the directors of the medical departments of the several colonies should communicate directly to each other detailed information about outbreaks of such diseases, and that the West African colonies should establish an epidemiological bureau, whose members could be authorized to act as liaison officers between the various Governments. Lastly, attention was drawn to the importance of organizing measures to prevent the introduction of epidemic diseases at land frontiers. It had to be recognized, however, that it was undesirable

[1] Report by Dr. P. S. Selwyn-Clarke on the Yellow Fever Conference at Dakar, 1928. Gold Coast: Government Printing Office, Accra, and from the Crown Agents for the Colonies, 4, Millbank, London, S.W.1. (Illustrated. 2s.)

to apply strict quarantine measures to ships and persons arriving from a colony where only isolated cases of yellow fever—namely, cases occurring at intervals of more than twelve days—had been reported.

PSITTACOSIS.

SINCE the publication last week of our note on psittacosis (p. 250), the Ministry of Health has issued a short memorandum on this subject for the guidance of medical officers to local authorities. The memorandum states that since July, 1928, some thirty or forty suspected cases of human psittacosis have been brought to notice in England, principally in Cheshire, Warwickshire, and the London district, all being associated to some extent with sick parrots. After a brief reference to the literature of the subject, it goes on to say that in general the disease in human beings takes the form of an illness, usually acute, with typhoidal and pneumonic symptoms. The pulmonary condition varies from a slight bronchial catarrh to massive consolidation of whole lobes of the lung; the "typhoid" symptoms may be severe or consist merely of headache and pyrexia, though frequently epistaxis, rose spots, abdominal distension, and, sometimes, diarrhoea are also present. The presence of the organism named *B. psittacosis* by Nocard in 1892, and shown by Perry in 1920 to be identical with *B. aertrycke* (Mutton), has not been established so far in any of the recent English cases or in the birds associated with them. The possibility of some or all of the cases being attributable to another bacterial species is being investigated in several laboratories. There is some evidence pointing to a filterable virus in certain of the London cases,[1] though it is as yet too early to say what significance these discoveries may have. The usual history is that a patient with an illness resembling typhoid, or more rarely with an atypical pneumonia, is found to have been in close contact with a sick parrot (more rarely a parrakeet or love-bird). The chief symptoms in the parrot are nasal catarrh and diarrhoea, which may be infective. Some reported cases where there has been exposure to bird infection on a single date suggest that an incubation period in the person attacked has been as long as ten days. Transmission of the disease from one human being to another has been suspected from time to time, but has not been definitely proved to occur. Cases of human illness so far reported appear to have been infected by recently imported birds, though in at least one instance the parrot is believed to have been in this country for some five months before falling ill. It is alleged that most of the birds associated with recent human cases in England have been of South American origin, but their history is not usually traceable with any certainty. The duration of the disease and its incubation period in the parrot are uncertain. Discussing precautionary measures, the memorandum says that nothing in recent occurrences gives any ground for apprehending danger from domestic parrots or other cage birds of the parrot family which have been kept in a household for many months or years apart from any introduction of new birds. On the other hand, this cannot be said as confidently of most newly purchased birds. Hence, until further investigations have cleared the situation, it is not unreasonable for the public to be chary of buying birds which have recently arrived in this country or whose history is unknown to the purchaser. Simple precautions in regard to cleanliness of cages, removal of sick birds, and disinfection of cages, etc., are advised, and a timely warning is given against fondling and petting newly acquired birds. Recent cases of presumed psittacosis have been under careful investigation by clinicians and pathologists, more particularly in the Birmingham area and in London. Medical officers of the Ministry of Health have taken part in certain of these inquiries, and efforts are being made to collate and study all the data available. When such cases come to light the following points of essential detail should be ascertained and noted by the medical attendant: (*a*) nature and period of association between the human case and the parrot, and the directness of contact; (*b*) history of bird, with dates; (*c*) date of attack in patient, and symptoms; (*d*) any evidence of association of patient with previous human cases. Such information regarding suspected cases of psittacosis would most conveniently be given to the local medical officer of health, but if desired it can be communicated direct to the senior medical officer (Med. 1), Ministry of Health, Whitehall, S.W.

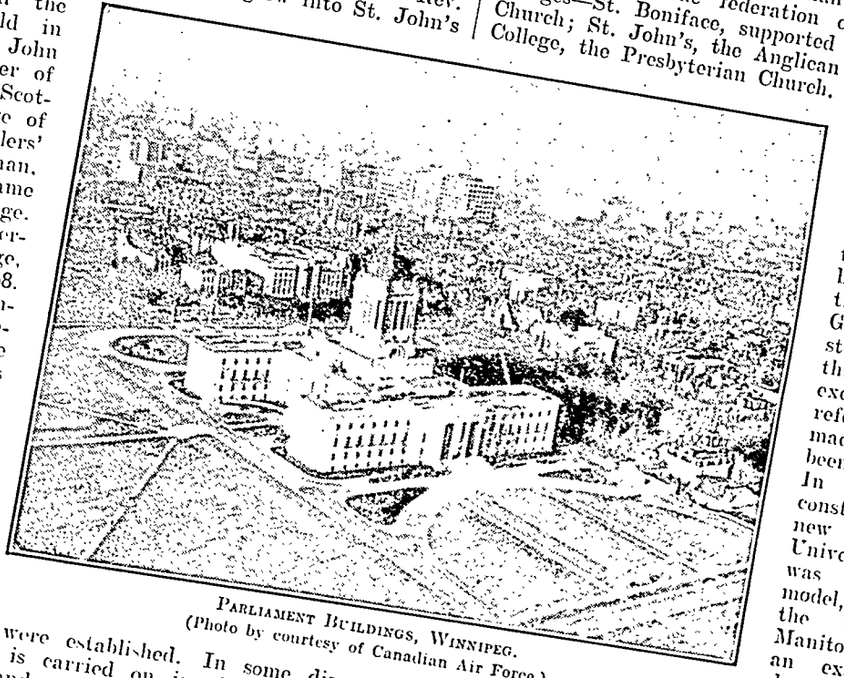
STERILIZED CATGUT.

IN an annotation dealing with surgical catgut, in the *Journal* of November 16th, 1929 (p. 918), reference was made to the addition of this preparation to the list of substances controlled under the Therapeutic Substances Act. Regulations have now been framed to ensure the sterility of catgut; they will come into operation on March 1st. It is enacted that before any ligature or other form of binding material prepared from gut or other animal tissue is "offered or intended to be offered for sale as sterile and ready for use in surgical operations upon the human body" tests for sterility according to the schedule shall have been satisfactorily applied. The regulations, including the method of performing the sterility test, have been published in leaflet form (Statutory Rules and Orders, 1930, No. 26), and may be obtained from H.M. Stationery Office, price 1d.

ROYAL COLLEGE OF PHYSICIANS.

THE Milroy Lectures before the Royal College of Physicians of London, on the incidence of rheumatic disease, will be delivered on February 27th and March 4th and 6th by Dr. J. A. Glover. The Goulstonian Lectures, on the significance to clinical medicine of studies in calcium and phosphorus metabolism, will be given by Dr. Donald Hunter on March 11th, 13th, and 18th. Dr. Carey F. Coombs will deliver the Lumleian Lectures, on syphilis of the heart and great vessels, on March 20th, 25th, and 27th. The Oliver-Sharpey Lectures, on diabetes as a physiological problem, will be given by Professor J. J. R. Macleod on April 29th and May 1st, and Sir Charles Martin will deliver the Croonian Lectures, on the thermal adjustment of man to external conditions, more particularly those pertaining to warm climates, on June 12th, 17th, and 19th. The lectures, to which any member of the medical profession is admitted on presentation of visiting card, will be delivered at the College, Pall Mall East, S.W.1, at 5 p.m. on each day.

AT a meeting of the Royal Statistical Society, at 5.15 p.m. on Tuesday, February 18th, in the hall of the Royal Society of Arts, John Street, Adelphi, W.C., Professor M. Greenwood will read a paper on the vaccination problem, dealing particularly with the work of Jenner, the nature of the statistical evidence in favour of vaccination, the epidemiology of small-pox, and the various hypotheses explaining changes in the epidemiological type.



A PUBLIC lecture (with lantern illustrations) on the infirmary of the mediaeval monastery, with special reference to the Abbey of Westminster, will be given at University College, London, by Mr. Percy Flemming, F.R.C.S., emeritus professor of ophthalmic medicine and surgery, on Friday, February 21st. The chair will be taken at 5.30 p.m. by the Dean of Westminster.

NINETY-EIGHTH ANNUAL MEETING of the British Medical Association, WINNIPEG, 1930.

AT the invitation of the Canadian Medical Association, the ninety-eighth Annual Meeting of the British Medical Association will be held in Winnipeg next summer, under the presidency of Dr. W. Harvey Smith, Professor of Ophthalmology in the Manitoba Medical College, who will deliver his address to the Association on the evening of Tuesday, August 26th. The scientific and clinical business of the meeting is being organized in fourteen Sections, which will hold their sessions on Wednesday, Thursday, and Friday, August 27th, 28th, and 29th, the mornings being given up to discussions and the reading of papers, and the afternoons to demonstrations and special addresses. The names of the Officers of Sections are given in this week's *Supplement*, together with other preliminary information, and further details of the arrangements will appear from time to time in later issues. Members who propose to take part in the meeting should write for particulars about the journey by sea and land to the Financial Secretary and Business Manager, B.M.A. House, Tavistock Square, London, W.C.1. The Winnipeg office is at 102, Medical Arts Building, Winnipeg, Manitoba. We publish below the second of a series of historical and descriptive articles on Winnipeg and its institutions, contributed by Dr. Ross Mitchell; the first appeared on January 4th (p. 32).

MANITOBA'S EDUCATIONAL INSTITUTIONS.

EVEN from the early years of the Red River Settlement attention was given to education. In those early years the Churches led the way, later the State became predominant. In 1819 the first Manitoba school was opened by Father (later Bishop) Provencher, and four years later this school had expanded to become St. Boniface College. In 1820 an Anglican school was established by the Rev. John West. This school afterwards grew into St. John's College. The Presbyterians entered the educational field in 1851, when Rev. John Black, a minister of the Church of Scotland, took charge of the Selkirk settlers' school at Kildonan, which in time became Manitoba College. Wesley Hall, afterwards Wesley College, was dedicated in 1868. In 1870 the government of the settlement passed from the hands of the Hudson's Bay Company and the new province of Manitoba was formed. The Provincial Legislature in 1871 formed a Board of Education in two sections—Protestant and Catholic. In 1890, after much agitation, free non-sectarian public schools were established. In some districts bilingual teaching is carried on in the primary schools. Both primary and secondary schools and also the University are under the control of the Government. The people of the province have always supported the schools loyally.

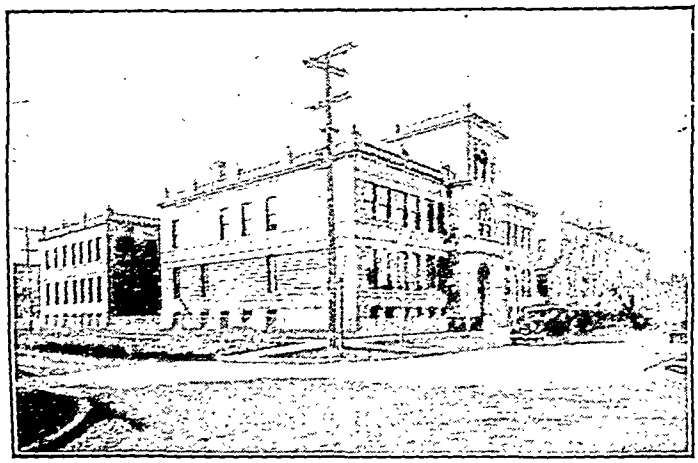
THE UNIVERSITY OF MANITOBA.

Properly to understand the position of Manitoba's University, one must realize three facts: first, that it originated in 1877, only seven years after the purchase by Canada from the Hudson's Bay Company of that vast district then known as Rupert's Land; secondly, that at the time of its founding the population of Manitoba, including Indians, was less than 65,000; and lastly, that it arose from the federation of three denominational colleges—St. Boniface, supported by the Roman Catholic Church; St. John's, the Anglican Church; and Manitoba College, the Presbyterian Church. Each of these colleges in that time and for several years had a hard struggle for existence. Manitoba has never been a wealthy province, and the University has been dependent on the support of the Government and students' fees. With three or four notable exceptions, to which reference will be made, there have been no endowments. In determining the constitution of the new University, the University of London was taken as the model, and until 1900 the University of Manitoba was merely an examining and degree-conferring body, all the teaching being done by the constituent colleges. Yet at the present time the University of Manitoba is the second in Canada in point of numbers of students enrolled—about 2,500—and there are 4,733 graduates in arts, theology, medicine, law, engineering, and agriculture.

When one reflects upon the large part that religious and denominational differences played in those early days—as, for example, the Manitoba school question, which caused a tremendous upheaval throughout Canada and led to the defeat of a hitherto strongly entrenched Federal Party—it says much for the breadth of vision and magnanimity

of the founders of the University that the progress of the institution has been comparatively so untroubled.



The first degree, that of Bachelor of Arts, was conferred in 1880. The first Master of Arts degree was conferred in 1884. After six years of discussion women students were first admitted to the University College in 1886. In 1883 the Manitoba Medical College was organized, and became affiliated with the University. In the following year a reading course in Law was arranged by the University and the Law Society jointly, and the first LL.B. was obtained in 1886. Wesley College represented the Methodist Church, and was affiliated in 1886.

The question of finances soon obtruded itself on the attention of the University Council. The Act of 1877 provided that a sum not exceeding 250 dollars should be placed at the disposal of the council of the University to meet the expenses incidental to the organization of the same. It did not seem to be realized that the University as constituted would need support from the public treasury beyond organization expenses. Nevertheless small grants were made annually. In 1887 the financial clause in the University Act was amended to read: "A sum not less than two hundred and fifty dollars shall be placed annually at the disposal of the University for the working of the same." This minimum had been granted from 1877 to 1884. It was then gradually increased until in 1890 it reached 3,500 dollars for the first time. It remained at that level until 1900. Between 1884 and 1889 the University revenue was increased by the assignment to it of the marriage licence fees which were earmarked for it by the Government.

In 1883 Dr. A. K. Isbister, a native of the Red River Settlement, bequeathed to the University 83,000 dollars for a scholarship fund. To this day Isbister Scholarships from this trust fund are being awarded. In 1878 application was made to the Dominion Government for a land grant as an endowment. For seven years this request of the University Council was urged upon the Dominion Government, and finally, in 1885, one hundred and fifty thousand acres of fair average quality were granted. The allocating of the land took another six years, and it was not until 1898 that the patents were issued, and it was 1900 before any revenue was derived.

In 1899, after prolonged discussion, the University Council decided that the University should become a teaching body. Chairs were to be established in natural science, mathematics, and modern languages. The Manitoba Government of that day pointed out that the establishment of a University staff carried with it the necessity of choosing a site for the University and the erecting of a permanent building. When approached, however, the Government was unwilling to take any definite action. As a temporary expedient, a property of 6.6 acres fronting on Broadway, recently conveyed by the Dominion Government to the Province of Manitoba, was placed at the disposal of the University, and on this, in 1904, a science building was erected. The corner-stone was laid by the Duke of York, now King George V. The building was made possible by the donation of $20,000 from Lord Strathcona. The Faculty of Science was organized at that time with six professorships.

The next few years saw the evolution of the University from a federation of denominational colleges to a provincial university. In 1907 the University Council asked the Government to appoint a Commission to investigate and report. In 1910 the Commission reported that its members had been unable to agree as to the extent of control of the University by the province. In spite of delays and disappointments, however, the University was growing, and a distinct step forward was made when a president was appointed—Dr. James Alexander MacLean, who still holds office. The question of a site was in 1905, and still continues to be, a vexed question. Three sites offered themselves—the small Broadway site, within the city; the Tuxedo site, about five miles from the centre of the city, and opposite the city's largest park; and the Agricultural College site, about seven miles from the centre of the city, but adjacent to the fine buildings of the Agricultural College, which had been erected by the Provincial Government at a very considerable expense. The Tuxedo Holding Company, in 1905, offered to donate 150 acres to the University on condition that the University should spend a certain amount on improvements and buildings. In 1916 the offer was repeated, to hold good for a term of ten years. The University Council voted to accept the offer, but the Government was opposed. In 1913 the Government, which at first had held out for the Broadway site, offered a tract of 137 acres between the Agricultural College and the Red River, and agreed to erect and equip an engineering building. August, 1914, however, saw the beginning of the great war, and a further postponement was necessary. It became increasingly plain that the University could continue to function most completely only as a provincial institution, and in 1917 control of the University was vested in a board of governors appointed annually by the Government, and responsible to the Government. During these years the University had been making progress. A course leading to a degree in pharmacy was established in 1905. In 1907 the Manitoba Agricultural College was affiliated with the University. In the same year a department of civil engineering was formed, and in 1909 a department of electrical engineering. Professorships of political economy, history, and English were also created in that year. In 1913 chairs were established in French, German, and architecture; and in 1914 departments of classics, pathology, and pharmacy were organized. In 1917 the Faculty of the Medical College agreed to transfer their buildings and equipment to the University on condition that the University carried on a Faculty of Medicine in an efficient manner. A department of philosophy and psychology was added in 1920.

FACULTY OF MEDICINE, UNIVERSITY OF MANITOBA.

The question of accommodation was temporarily met by the erection of a building to the north of the science building, by the utilization of the old school for the deaf, and the old law courts, and by the erection, during 1920–22, of temporary buildings on the Broadway site. A grant from the Rockefeller Foundation enabled a new medical building to be erected west of the General Hospital.

During the last session of the Provincial Legislature the Government appointed a University Committee from members of the Legislature to consider the question of a site and new buildings. This committee has now reported unanimously in favour of the Agricultural College site, and has recommended that a building to cost one million dollars be erected thereon to provide for the needs of the senior years of the University, while the junior years will be housed temporarily on the Broadway site within the city.

The report of the committee will be presented to the Legislature at its forthcoming session; nothing can definitely arrest the progress of a university which in a little more than fifty years, and in the face of tremendous obstacles, has come to occupy such a prominent place in the educational history of the Dominion, but a wise and liberal policy on the part of the Provincial Government will accelerate its advance and enable the University of Manitoba to take its rightful place in the cultural life of the community.

MANITOBA'S MEDICAL SCHOOL.

Manitoba Medical College may be said to owe its origin to the importunity of the medical students. In 1882 Winnipeg was a pioneer prairie town, the famous boom was at its height, and there were tremendous hopes for the future. A group of intending medical students, headed by John Fawcett, principal of the high school, called upon Dr. Agnew, and requested him, as one-time professor of the principles and practice of medicine at Victoria College, Toronto, to take steps to commence medical teaching in Winnipeg. As a result a meeting of the College of Physicians and Surgeons of Manitoba was held to discuss this proposal, but it was decided that the time had not yet come for the commencement of a medical school in Winnipeg.

In July, 1883, a young doctor, scion of a distinguished family, arrived from Toronto, and announced his intention to start a proprietary medical school. This project was energetically resisted by the doctors resident in the city, the leader being Dr. James Kerr. Dr. Kerr was a colourful personality. A native of County Antrim, he had taken part in the Ashanti campaign under Sir Garnet Wolseley in 1873–74, was a close friend of Osler and Shepherd of McGill, and a disciple of Lister. In the controversy over the Medical School he maintained two principles—first, that the established practitioners should be the founders; and second, that the granting of degrees should rest solely with the University and not with the Medical School. After two months' fight agreement was reached among the medical practitioners, and the Legislature of Manitoba was requested to grant a charter incorporating the Manitoba Medical College. Thirteen physicians, headed by Dr. Kerr, were named as incorporators.

The intention of the medical profession was that, once having obtained a charter which would preclude the starting of other medical schools in the province, nothing would be done until a more opportune time. Once more, however, the medical students came upon the scene, and, pointing out the hardships and expense consequent upon their attendance at medical schools in Toronto or Montreal, requested earnestly that the school be opened that fall. Circumstances did not seem auspicious, but the insistence of the students prevailed, and, after many difficulties had been surmounted, Dr. Kerr, who had been chosen dean, delivered the introductory lecture on November 15th, 1883; in that lecture the professors in the primary subjects were announced as follows: anatomy, Drs. Codd and Blanchard; materia medica, Dr. R. G. Brett; chemistry, Mr. John Fawcett; physiology, Dr. A. H. Ferguson. A word or two concerning the subsequent careers of some of these men may not be out of place.

Dr. Blanchard, who with Dr. John Stewart of Halifax had been one of Lister's dressers at Edinburgh, became a leading surgeon of Western Canada, a president of the Canadian Medical Association, and died in September, 1928, universally beloved. Dr. R. G. Brett moved to Banff in 1886, established a sanatorium at the sulphur springs, interested himself in public life, became Lieutenant-Governor of Alberta, and died on September 16th, 1929. Dr. A. H. Ferguson, after a notable career as a surgeon in Winnipeg, moved to Chicago, where in this wider sphere he made a notable name, particularly in the field of hernia.

At first the school had no settled abode, and various places were utilized. In 1884 the Faculty put their hands into their pockets and arranged for the building of a school at McDermot and Kate Streets, not far from the General Hospital. In this building, with additions, work was carried on until 1906, when a building was erected on the present site immediately to the west of the General Hospital.

In 1887 Dr. Kerr moved to Washington, D.C., and Dr. J. W. Good, one of the first in Canada to specialize in diseases of the eye, ear, nose, and throat, was appointed dean in his stead. In 1900, Dr. Good having joined the trail of '98 to the Yukon, Dr. H. H. Chown, a distinguished graduate of Queen's University, succeeded him and held office until 1917, when he became a member of the first board of governors of the University. Dr. S. W. Prowse, a native of Prince Edward Island, a graduate in medicine of Edinburgh University, and in 1917 the commanding officer of a casualty clearing station in France, was appointed dean, and still holds that office. During all these years the college had been self-supporting, owing to the disinterested action of the Faculty, with the exception of the full-time professors, in refusing to accept any remuneration. Up to 1918 the Medical School, though a constituent college of the University, and though all medical degrees were granted by that body, could at any time have withdrawn from the University. The unselfish and statesmanlike policy of Dr. Chown led to the college becoming, in 1918, an integral part of the University, transferring by deed its unencumbered property and equipment to the larger body on condition that the University establish a Faculty of Medicine and carry on the work of medical education in an efficient manner. The college then became the Faculty of Medicine of the University of Manitoba.

At the present time 275 students are registered, and since 1923 the school has had Class A rating. The course lasts five years, four years being spent in class work, while the fifth is a purely clinical year, the student being an intern at a recognized hospital. Graduates of the school may justly feel a thrill of pride in reflecting that from humble beginnings their Alma Mater is now recognized as one of the leading medical schools of the Dominion.

CARBON MONOXIDE POISONING.

AN AMERICAN MEMORANDUM.

On behalf of the American Medical Association's Committee on Poisonous Gases Dr. Yandell Henderson of the department of applied physiology in Yale University Medical School has drafted a memorandum entitled "The dangers of carbon monoxide poisoning and measures to lessen these dangers," which was published in the *Journal of the American Medical Association* of January 18th (p. 179).

The memorandum opens with an account of the conditions favouring the production of carbon monoxide. The combustion of organic materials tends to take place in two stages: the first producing carbon monoxide, the second carbon dioxide. Only the first stage is completed if the supply of air to the burning material is insufficient to provide the extra molecule of oxygen, or if the temperature of the gas, when it reaches the outside air, is too low to favour the second oxidation. In a coal fire, if the air supply is checked in any way, carbon monoxide may be produced by the reduction of carbon dioxide as it passes from the lower layer of red-hot coal through the upper, cooler layers. Yet a third way in which carbon monoxide may be formed occurs in the gas stoves used for cooking and in water heaters. Where natural gas is not available the manufactured gas supplied in most American cities usually contains about 20 per cent. of carbon monoxide. But even when natural gas, consisting of methane, is burned, the combustion may be stopped at its first stage by the chilling of the flame when it comes near a cooking utensil, or a pipe containing cold water, and, as a result, large amounts of carbon monoxide may thus be liberated. The death of persons sleeping in closed rooms containing such a stove or water heater is usually attributed to "exhaustion of oxygen in the air by the fire." This explanation is incorrect, as the flame would cease to burn in air in which the percentage of oxygen was reduced to 16 per cent., a far greater oxygen deficiency being needed to endanger life. All such fatalities are due to carbon monoxide, of which a

concentration of even a few tenths of 1 per cent. is sufficient to cause death. The defect in cooking stoves could be partially overcome by increasing the distance between the orifice of the gas burner and the cooking utensil or water pipe; these should be just above, not in, the visible flame. In burning buildings carbon monoxide is produced in large amounts, and in fires and explosions in mines carbon monoxide may cause more deaths than the explosions or the fires themselves.

Asphyxiation by Coal Gas.

Manufactured gas in American cities—"city gas"—is produced in two ways: (*a*) by the destructive distillation of coal, producing "coal gas" containing about 7 per cent. of carbon monoxide; (*b*) by blowing steam through red-hot coal, producing "water gas" containing 40 per cent. carbon monoxide. Commonly used is a mixture of these two products with vaporized petroleum, containing about 20 per cent. of carbon monoxide.

The problem of decreasing the number of deaths from city gas is largely economic; it costs more per cubic foot to manufacture gas of low than of high carbon monoxide content, but the difference in cost per heat unit of the two kinds of gas is much less than that per cubic foot. The public could further the introduction of city gas of higher calorific and lower carbon monoxide content by supporting efforts to fix the price of gas on the basis of the heat unit rather than of the cubic foot. It is probable that in future, as the use of gas for heating homes becomes even more prevalent, higher pressures will be needed in the pipes in the street, and reducing valves will be fitted on the supply to each house. In these circumstances a leak or a defective valve would be even more dangerous than it is at present. It is possible, however, that scientific advances may lead to the manufacture of a moderately priced gas low in carbon monoxide and high in calorific value. Still more advantageous would be the development of methods for manufacturing a fairly cheap liquid fuel from coal, and Dr. Yandell Henderson suggests that investigation directed to the development of methods for the manufacture of such a gas or liquid fuel deserves liberal financial support by the gas industry.

Much of the mortality from carbon monoxide poisoning Dr. Henderson attributes to the carelessness of public health authorities. If all the cases of gas poisoning in the United States were distributed into groups according to their common causes each group would show a definite mortality per 100,000 of population; a group in which asphyxiation results from using flexible hose that is old and defective or is accidentally disconnected; a group in which the tea kettle has boiled over and put out the fire; a group in which the hot-water heater is without a flue. Each group will continue to take its regular fraction of the fatalities until a general change in conditions is enforced by the public health authorities. The public health bureaux, public service commissions, and the building and plumbing inspection services of cities can do much by making and enforcing regulations against the sale to the public of badly made and unsafe appliances. All agencies should help to stop the use of flexible gas pipes; in homes gas should be burned only in appliances with fixed connexions. The municipal building and plumbing bureaux should insist on hot-water heaters being connected to flues. Above all, the gas industry should aim at reducing the amount of carbon monoxide in city gas. If it were reduced by one-half, the number of accidental deaths from gas would be reduced to a fourth, or less, of the present mortality.

Poisoning from Exhaust Fumes.

The internal combustion engine used in motor vehicles and aeroplanes gets its power from the explosion of air and petrol under pressure. The combustion occurring under these conditions is never complete, and the exhaust gas always contains an amount of carbon monoxide, varying according to the proportion of air and petrol vapour. When rich mixtures are used the amount of carbon monoxide in the exhaust gas may be as much as 7 per cent., and as a rough figure Dr. Henderson suggests that for each 20 h.p. of the motor, run on the usual mixture, one cubic foot of carbon monoxide is produced each minute. If this amount is discharged for five minutes into a small garage (cubic capacity of 2,000 cubic feet) the resulting concentration in the air rises to about a quarter of 1 per cent. Such an amount is sufficient to paralyse a man in a few minutes, and to produce death if he is not removed from the poisonous atmosphere within a short time. On account of this danger warnings should be issued each year, before the cold weather begins, against starting the engine of a car before opening the garage doors. Persons take risks under the impression that they will feel some effect, which will act as a danger signal; but carbon monoxide gives no warning. Often its first effect is a sudden muscular weakness, which causes the victim to fall helpless to the floor. For large garages the local authorities should enforce regulations against the discharging of exhaust gas from any car into the air of the garage for more than a short time; if this regulation is not enforced no amount of artificial ventilation will keep the air of the garage healthy. Dr. Henderson suggests that the use of the vertical exhaust on taxi-cabs and on commercial vehicles may, in congested traffic, do much to diminish the contamination of the air with exhaust gas.

Poisonous Action of Carbon Monoxide.

The poisonous action of carbon monoxide is due almost entirely to the fact that it combines with haemoglobin, and thus deprives the body of oxygen. Affinity of haemoglobin for carbon monoxide is more than two hundred times as great as for oxygen; but though the blood becomes highly charged with carbon monoxide, even when air containing only a few hundredths of 1 per cent. of carbon monoxide is breathed for a considerable time, the carbon monoxide, owing to the looseness of its combination with haemoglobin, may, in the presence of sufficient oxygen, be readily driven out of the blood again. If, however, there is much delay in replacing carbon monoxide ill effects may follow, especially intense headache, due to oedema of the brain, and occasionally impairment of the heart and nervous system. These effects are secondary to the injury done to the brain and to the heart when carbon monoxide was temporarily excluding oxygen from the blood; they are, in short, after-effects of asphyxia.

Generally, a person who has been partially asphyxiated by carbon monoxide recovers completely if he is resuscitated in time; less acute, but more prolonged, are the effects of repeated exposure to small amounts—such as a cook, working in a small, badly ventilated kitchen, with a defective gas stove, may breathe day after day. For such low-grade intoxications the only proper treatment is the improvement of the conditions under which the persons concerned live and work.

Gas Masks.

Each gas, or type of gas, has its own particular absorbent or catalyst, and a mask deficient in the requisite substance, or used too long, or allowed to get into disrepair, affords no protection. The so-called "all-service mask," containing some of each absorbent and catalyst, protects against practically all gases, but only for a short time. A wet handkerchief tied over the face gives no protection whatever against carbon monoxide; no mask of the absorbent type gives protection against an atmosphere deficient in oxygen. The best test for the quality of an atmosphere is afforded by a mouse or a canary; these small animals are overcome far more quickly than man, and thus give timely warning of danger. The safest form of mask is the so-called hose mask, in which a long hose is connected at one end to the mask, and at the other to an air pump. An assistant outside the gaseous chamber works the pump so as to supply fresh air to the man wearing the mask; the self-contained oxygen apparatus is liable to dangerous defects, and should never be used except by specially trained men, and even by them never when the other forms of mask will serve.

Method of Resuscitation from CO Poisoning.

The object of inhalational treatment is to eliminate carbon monoxide from the blood as soon as possible. It derives its value from the fact that carbon monoxide asphyxia, if untreated, may continue in almost full force for a long time after the victim has been removed from the poisonous atmosphere. If the victim is not breathing, artificial respiration by the prone pressure method should be started without delay and continued until spontaneous breathing returns or death is fully established. Inhalation of oxygen and carbon dioxide is a valuable adjunct to artificial respiration. If the victim is breathing, artificial respiration should not be attempted, but inhalation of oxygen and carbon dioxide, or, if these are not available, of oxygen only, should be started at once. The patient must be kept warm, and on no account handled roughly. After the return of spontaneous breathing the inhalation should

be continued till the patient's condition is once more virtually normal. The practice, formerly common, of making a partially resuscitated person walk, may injure the heart; unless, therefore, the patient is fully restored to normal, he should be prevented from making any exertion, even from sitting up. Blood transfusion, says Dr. Henderson, is quite useless; continued coma is due to oedema of the brain and to other post-asphyxial injuries to the nervous system, and these are not benefited by blood transfusion.

Inhalational Treatment.

The inhaler usually consists of one or two cylinders of oxygen under pressure, with which 7 per cent. of carbon dioxide has been mixed. The victim of asphyxia is made to breathe this mixture of gases by means of a mask and suitable valves. To ensure prompt treatment Dr. Henderson suggests that every hospital should have such inhalers as part of its equipment, and that one should be carried by every ambulance. Carbon dioxide is added to the oxygen in the inhaler to stimulate deep breathing; it thus causes a larger volume of oxygen to be inhaled, and helps in displacing carbon monoxide from the blood. Whereas in cases of moderate severity carbon monoxide may be almost entirely eliminated within half an hour by inhalation of oxygen alone, in serious cases oxygen may fail to bring about recovery. An additional reason for the use of carbon dioxide is that oxygen, having no displacing action of poisonous gases other than carbon monoxide, is of little benefit in the treatment of persons who have been overcome by other toxic vapours—for example, those of methyl alcohol, petrol, and benzene. Inhalation of carbon dioxide in these cases induces a rapid ventilation of the poison out of the body by way of the lungs.

Among the further advantages of using carbon dioxide mixed with oxygen Dr. Yandell Henderson claims the following: (*a*) full dilatation of the lungs after asphyxia tends to prevent subsequent pneumonia; (*b*) inhalation of carbon dioxide rapidly restores the acid-base balance of the blood and the body tissues, which under asphyxia is profoundly disturbed; (*c*) the inhaler may be used in the treatment of asphyxia neonatorum, the stimulation of the respiratory centre by carbon dioxide setting the machinery of breathing in operation. In the treatment of pulmonary oedema induced by irritant gases oxygen should be used without carbon dioxide.

HEALTH OF THE ARMY.

REPORT FOR THE YEAR 1928.

SOME years ago the annual report on the health of the army was remodelled and condensed, so as to bring out its salient statistical features and direct attention to the medical and surgical technique that had been practised in the army. These reports add a valuable contribution to the medical literature of the year. The report for 1928,[1] following familiar lines, has been published within the accustomed period of thirteen months, and medical officers are fortunate in having such a concise and modern statement to guide them in their professional work. To civil members of the profession the report should also prove of interest, as many societies and individuals appreciate reliable information about diseases which cause inefficiency in work and the benefits derived from well-thought-out methods of prevention.

The year 1928 has been the healthiest in the army since the war. The admission ratio has fallen from 467.7 in 1927 to 426.2 per 1,000 of the strength, which is the equivalent of a daily sick rate of 0.12 per cent., and probably represents a normal sick rate among a selected population, comfortably housed, well fed and clothed, systematically trained and constantly supervised by medical officers with special knowledge of preventive medicine. If the sick rate is analysed it will be found that there are three outstanding features. The first is the influence played by the commoner diseases of everyday life. Expressed as ratios per 1,000 of strength, diseases of the digestive system are responsible for 80.4; local and general injuries 53.3; venereal diseases 39.3; septic conditions 36.9; diseases of the skin 22.8; diseases of the respiratory system 18.3; and influenza 8.8; or a combined total of 269.8 out of the admission ratios for the year. The next salient point is the negligible effect on the admission rate of the ordinary infectious diseases, the ratios of which per 1,000 were: scarlet fever 1.6; mumps 1.4; measles 1.2; diphtheria 1.0; enteric 0.9; meningococcal infection 0.1; and small-pox 0.1; while the more virulent diseases of the East—namely, cholera, typhus, relapsing fever, and plague—are absent altogether. The third concerns two diseases which are known and perhaps feared in every household in the land—namely, pneumonia and pulmonary tuberculosis. They have an almost standardized but small ratio in the army, the former being 2.6 per 1,000 in 1928 and the latter 1.1. The reduction in the admission ratio for the year has been due to a decrease in the admission rate for malaria from 49.5 in 1927 to 35.7; for venereal diseases from 49.1 to 39.3; and for influenza from 24.1 to 8.8. Dysentery remains approximately the same. While the total figures for venereal diseases are reduced, the percentage of cases of gonorrhoea—namely, 69.8—remains practically the same as for the known cases occurring during the war and for the year 1927. It will be seen that if any great reduction in the sick rate is to take place in the future it must be by a decrease in the number of cases admitted for the commoner diseases. This offers a wide field for research, a field dulled perhaps by familiarity, but yet worthy of constant investigation by medical men, whether civil or military, if the science of medicine is to reduce the inefficiency caused by disease among civilian and army personnel, both at home and abroad.

The number of invalids discharged from the army during 1928 was 1,661, or 9.06 per 1,000 of the strength. This figure is approaching the lowest pre-war rate of 7.8 in 1913. The principal causes of invaliding were inflammation of the middle ear (246 cases) and tuberculosis (207 cases). We are glad to note that the medical directorate is alive to the need of careful examination for these conditions on enlistment and before service overseas, since continuation of the service in doubtful cases can only lead to further trouble to the individual, expense to the State, inefficiency in a unit, and the invaliding of the affected persons.

Medical officers have special opportunities for research work in different parts of the world, and some, like Leishman and Bruce, have become world-famed. For a time the incentive seems to have been lacking. It is all the more gratifying to note, therefore, that attention is being directed to the elucidation of dysenteric infections and pyrexias of three to seven days' duration.

Section II of the report, dealing with the special departments of medicine, surgery, hygiene, pathology, dental treatment, and the medical examination of recruits, gives a general survey of departmental work throughout the year. Section III, apart from the chapter on India, is composed mainly of standard statistical tables showing the incidence of disease in the different commands. The chapter on India is of great educational value, and should be carefully studied by senior and junior officers.

Ireland.

Dr. Steevens's Hospital, Dublin.

THE provost of Trinity College presided at the opening of a special ward in Dr. Steevens's Hospital, Dublin, for the treatment of patients suffering from tuberculosis and other bone diseases. Dr. T. P. Kirkpatrick, reviewing the history of the hospital, described how Richard Steevens, the son of an English clergyman who came to Ireland in the seventeenth century, graduated at Trinity College and became president of the College of Physicians in Dublin. On December 14th, 1710, Dr. Steevens made his will and died on the following day. He left £600 in trust for his sister for her lifetime, the proceeds, after her death, to go to the building of a hospital in Dublin. There was at the time no hospital for treating the sick poor, and in providing for one Dr. Steevens created a precedent in the city. In 1717, Dr. Steevens's sister executed a deed giving the trustees £2,000, which included some of her own money, to buy a site for the

hospital. The trustees were prominent citizens of Dublin, and in August of that year they met at the Archbishop's Palace, now the police barracks in Kevin Street, to consider the purchase of a site. Almost at once they began to clear and enclose the site, and in 1720 the building proper of the hospital was commenced. The building proceeded so rapidly that in 1726 the governors met there. In 1733 it was opened for patients, and since then patients had been received daily without interruption. In 1803 the top landing was taken over by the Government for the use of sick soldiers, and it was calculated that they could accommodate 200 patients; it was now proposed in that ward to accommodate some twenty to twenty-five patients. The military forces remained in occupation of that part of the hospital until 1814. In 1818 an epidemic of fever broke out in Dublin, and this portion of the hospital was requisitioned by the Government, accommodation being provided for eighty-seven patients. During a period of one year and eleven months 4,777 fever patients passed through that hospital, and the mortality rate was lower than in any other fever hospital. The ward was then used for ordinary patients until 1843, when the Government asked for the top landing for Royal Irish Constabulary patients, and it was used for this purpose up to 1922, when the Constabulary was disbanded.

Experimental Science Association of Dublin University.

Professor Bigger, in the course of his presidential address, "America as seen by a scientist," which he delivered recently to the Experimental Science Association of Dublin University, said that Americans had good reason to be proud of their universities. He could not tell them much about the universities because he was chiefly interested in the medical schools, which were largely post-graduate institutions, less closely connected with the parent universities than was the case in European countries. In a sojourn of sixty-three days in America, he had visited eighteen medical schools, three post-graduate medical schools, three schools of hygiene, and ten other institutions where bacteriology and hygiene were studied. Practically all the schools visited were built on a similar plan—the H plan—which was capable of infinite extension, the school being in physical contact, as all medical schools should be, with the hospital. The block plan, almost universal, gave structural simplicity and ensured the strictest economy, but in many cases, as he illustrated by lantern slides, the buildings were extremely ugly, and economy had been carried to excess. There were, however, notable exceptions, such as the Northwestern Medical School, Chicago; the Jefferson Medical School, Philadelphia; and the Columbia University College of Physicians and Surgeons, at Medical Centre, New York. The last-named was a colossal pile, containing the largest medical building in the world. As one might expect in a wealthy country, the equipment of the schools was excellent. Their staffs, he found, were well above the minimum necessary for mere teaching. Possibly the most liberal allowance was in the bacteriology department of Columbia University, New York, where there was a staff of 23, 17 of whom were engaged in teaching 108 students; 17 technicians and 3 secretaries were also employed. Teaching occupied only a small proportion of the time of the professors—their other function was research. There might be a modicum of truth in the charge that what science in America demanded was results in the form of papers. What really was demanded was work, even if results were slow in forthcoming. Work, hard work, was the gospel there, not only for the teacher, but for the student. That impressed him almost more than anything else in America. Hard work was inspired chiefly by keenness and enthusiasm for the chosen subject. Those qualities did not make a genius, and he did not imagine that America would produce more geniuses than any other country, but it had produced more well-trained, able men. He found that the normal lecture was fast losing ground; where it survived it was purely optional. Practical classes were regarded as of more importance. The student was encouraged to learn for himself from his practical work, and especially from original sources. Those he saw were medical students, all of whom must have completed two years in the university, or in certain schools, before entering the medical schools. It followed that the American student was older than the student here, and, for the most part, was more serious about his work. Competition to enter the better schools was severe, and even a degree was no guarantee of being accepted. The American medical student was a picked man or woman, and care was taken to ensure that he or she maintained a high standard of work while at school. The chronic medical student did not exist in America. This selection of candidates was one of the greatest differences between American and British schools. In the more progressive schools the tendency was to cut down, as far as possible, the compulsory classes, and leave the student free to work out his own curriculum. The medical student led a hard life. Saturday afternoon seemed to be his only free time. On other days he worked from 8 till 4 or from 9 till 5, and frequently much longer. At many of the universities the students worked during vacations, and even during term, to pay their way through college. Professor Bigger touched on the methods of teaching—the replacement of formal lectures by less formal discussions. In America bacteriology and hygiene were tending to become non-medical, and the tendency would, he thought, be followed here. In America there were great opportunities for the young bacteriologist, not only in the universities, but also in the State and municipal laboratories. In Ireland, he thought, they were following the lead of America in the teaching of bacteriology and hygiene. Even now in Trinity College bacteriology might be studied by non-medical science students, and a course in hygiene was available for non-medical men and women. He hoped that hygiene would soon find a place in the college arts course. The enthusiasm of the American youth for education was extraordinarily stimulating; in this the universities were no exception. The president of the University of Chicago, installed a few months ago, was 30 years of age. America was prepared to rely upon her youth, and in that, he believed, lay the explanation of much of America's success. Old age commanded her respect only when it followed a life of work and achievement, such as that of Welch of Baltimore, or Theobald Smith of Princeton. What America hated was senility, especially premature senility. So long as America held these opinions it might make mistakes, but it would never stagnate.

Legalization of Sweepstakes for Hospitals.

A deputation, consisting of Sir Thomas Myles, Sir Conway Dwyer, Sir William Taylor, Dr. MacCartan, Dr. P. McArdle, and Sir James Craig, waited recently on President Cosgrave, and urged upon him the need of funds for the hospitals of Dublin, pointing out the excellent work in progress at these institutions. They were handicapped through lack of funds, and one of the methods by which support could be given was by the passage through the Dail of the Public Charitable Hospitals (Temporary Provisions) Bill, which received its first reading in the Dail before its adjournment at Christmas. The bill provides for the granting of powers to enable funds to be raised by means of sweepstakes and drawing of prizes for the support of public charitable hospitals and sanatoriums in the Irish Free State.

Fees for Medical Substitutes.

At a recent meeting of the medical practitioners of County Wexford resolutions were passed protesting against the fee of £5 5s. a week allowed by the Health Board, and sanctioned by the Department of Local Government and Public Health. In the circumstances it was decided to rescind a former resolution passed by the Wexford medical practitioners fixing the fee for temporary work at £6 6s. a week, and to accept under protest the fee of £5 5s. a week sanctioned by the Department of Local Government and Public Health. The meeting, however, decided not to accept a lower fee than £1 1s. a day for temporary work arising out of incapacitation from illness or other causes. The question of applying again to the Minister for Local Government and Public Health to fix an increased scale of salaries for the medical officers of the County Home, and the Enniscorthy, Wexford, and New Ross Unions dispensary districts by sealed order, was discussed, and it was

decided to ask the honorary secretary to call a meeting in February to consider the matter further. Dr. W. W. Murphy tendered his resignation as honorary secretary, which was accepted with regret, and Dr. E. G. Connolly was unanimously elected to succeed him.

Scotland.

Infectious Diseases under the Local Government Act.

A CIRCULAR has been issued by the Board of Health dealing with infectious diseases, including tuberculosis and venereal diseases, as the arrangements for these are affected by the Local Government (Scotland) Act, 1929. The local authority responsible for dealing with these diseases will be the town councils in large burghs and the county councils elsewhere. This will have little effect on infectious diseases services in large burghs, but county councils will in future be responsible for these services in the whole of their landward areas, as well as in the small burghs in various counties. It is pointed out that bacteriological science has revealed the causes of an increasing number of infections, and has consequently required the setting up of an extensive laboratory equipment, and the development of a complex technique; while an increasing range of curative serums for the specific treatment of these diseases has been made available. There must therefore be an adequate provision of hospital and laboratory facilities with the necessary expert and specialist services, and councils will have to give consideration to these broad requirements. It is pointed out that the control of infection in hospitals is a matter of hospital administration and hospital consideration, and that there is no reason why the hospital provision for infectious diseases should not be contiguous to the hospital provision for general diseases. A council which is still content to provide hospital accommodation only for scarlet fever, diphtheria, and enteric fever cannot be regarded as giving an adequate service for the treatment of infectious diseases, and the possibility of having to deal with such diseases as poliomyelitis, encephalitis lethargica, spirochaetal jaundice, and perhaps rheumatism, should be kept in view, as well as the need for additional beds for non-pulmonary tuberculosis, measles, whooping-cough, pneumonia, and diarrhoea. The problem which most county councils will have to face is not how to remedy an immediate shortage of beds, but how to make the best use of existing beds, which are scattered over the county in small hospitals belonging to district committees and the town councils of small burghs. It is now recognized that with improved travelling facilities the maintenance of a series of small infectious diseases hospitals serving districts in their immediate neighbourhood is no longer desirable or necessary, and that concentration of patients in larger hospitals should be the ultimate aim of councils, although it may take some years to bring this to completion. Where combination hospitals exist, councils should not take steps to withdraw from the combination. The medical officer of health should be responsible for the general supervision of hospitals under the control of each council, and in the larger institutions there should be a whole-time resident officer, while smaller hospitals may continue to make use of the part-time services of local general practitioners. There is no provision authorizing recovery of charges in respect of maintenance and treatment from persons suffering from infectious diseases, and this position remains unaltered by the new Act. As regards the notification of infectious diseases, after May 16th, 1930, practitioners will be required to send these to the county medical officer, who will be obliged to make a weekly return of such cases to the Board of Health. In regard to tuberculosis, the same arrangements hold good as for other infectious diseases, and it is suggested that efforts should be made to secure earlier notification of cases of tuberculosis than is common at present. It is pointed out that there is still room for the development of clinics in many county districts, and that rural centres for the use of various health services might be established. With regard to venereal diseases, the local authorities will be county councils and town councils in large burghs, as for other diseases. In large burghs the schemes will not be affected by the Act, but the transfer of powers to county councils will necessitate the co-ordination of existing provisions for diagnosis and treatment, and the medical officer of health will be the chief administrative officer for such schemes. The new authorities will have to determine whether it is necessary to provide further treatment centres within their areas. Copies of this circular, price 2d., may be obtained from H.M. Stationery Office, 120, George Street, Edinburgh.

Criticism of Health Services under the New Act.

A series of addresses on the Local Government (Scotland) Act, 1929, has been arranged by the Edinburgh Women Citizens' Association, and the first of these was given on February 4th by Sir W. E. Whyte. Councillor Mrs. Somerville presided. The speaker mentioned that as regards administration there would be 229 local authorities in Scotland, as against 1,340 prior to the passing of the Act. A matter of interest to outside bodies, such as the Edinburgh Women Citizens' Association, was the provision in the new Act for co-option of outside persons by local authorities. People with special knowledge and experience of a particular branch of public work might prove to be of great assistance to a particular committee. One of the strongest arguments put forward in support of the passing of the Local Government Act was that it would be possible to secure unified control for all health services, and at the same time to avoid overlapping. There had been a need for reform in connexion with health administration in Scotland. It was proposed to keep medical inspection of school children under the jurisdiction of the education committee instead of under that of the public health committee of local authorities. With two or more committees dealing with health services, it would not be possible for the chief medical officer of health to interchange staff or to do many other things which would be possible if the whole health services were under one committee. The proposal, therefore, to continue a separate executive staff under the education committee would not seem to be a practical one. It was difficult to see why the health department should not undertake the duty of medical inspection and general health supervision of school children, quite apart from educational interests. In some respects the same observations applied to the administration of public assistance. If the medical aspect of the matter were divorced from the general public health administration, and supervised by a separate committee, the whole scheme of reform would be endangered. There would have to be the closest working arrangements between the committees concerned.

Glasgow Western Infirmary.

The fifty-fifth annual general meeting of contributors to the Western Infirmary of Glasgow was held on February 5th in the Merchants' House. Lord Provost Kelly presided. The report shows that the total ordinary income for the past year was £72,639, an increase of £670 over that of the previous year, while the ordinary expenditure was £82,305, this being a decrease of £2,000. The total revenue of £94,418, including legacies, exceeded the total expenditure of £90,783, thus enabling the managers to carry forward to capital account £3,635. The patients treated in the wards during the year had numbered 12,521, and the out-patients had been 38,437. The average daily number of patients in the hospital had been 592, and the average cost per patient per day had been 7s. 6d., as against 7s. 10d. during the previous year. The number of deaths was 826, making a rate of 7.3 per cent. of all cases, and with the deductions of deaths that occurred within forty-eight hours of admission this death rate was reduced to 5.1 per cent. The report further states that a new x-ray and electrical department is nearing completion, and is expected to be in full working order within the next three months. An ophthalmic department, for which funds were provided by the trustees of the late Dr. Tennent in 1916, is to be built as soon as the managers of the Infirmary can obtain possession of some house property in the neighbourhood. The number of cases treated by radium during

the past year with the radium purchased by means of a gift of £5,000 from Sir Henry and Lady Mechan had been greater than in any preceding year, and was steadily increasing. Colonel John A. Roxburgh, chairman of the managers, stated that the only item in the subscription list showing any marked decrease was that of employees' subscriptions, which were lower by £400 than in the previous year. He also pointed out that the David Elder Infirmary, Govan, an auxiliary hospital to the Infirmary, was proving a valuable addition to its accommodation, and had already enabled the waiting list to be materially reduced. The speaker said that with the coming into force this year of the Local Government (Scotland) Act, changes would inevitably take place in the hospitals, and it was of the utmost importance that there should be co-operation and not overlapping between the voluntary and the rate-supported hospitals. Continuous consultation between those responsible for the two kinds of hospitals would be necessary. Some rearrangement in the working of the voluntary hospitals might be required, but there would not be any interference with the voluntary principle. Professor Robert Muir, in moving a vote of thanks to the various subscribers, referred to the recent purchase of radium for the Infirmary, which would enable surgeons to apply radium under favourable conditions in the treatment of malignant diseases, and at the same time would enable a search to be made for improved methods of technique in exploring to the fullest degree the possibilities of treatment by radium.

Edinburgh Orthopaedic Clinic.

A new orthopaedic clinic was opened at 60, Pleasance, Edinburgh, on February 7th, by the executive committees of the Pleasance Trust and of the Chartered Society of Massage and Medical Gymnastics. The Very Rev. J. Harry Miller, D.D., presided. Miss Gertrude Herzfeld, F.R.C.S., explained that the work at this clinic had been inaugurated by members of the Chartered Society of Massage and Medical Gymnastics, which felt that there was a large gap between work at the hospitals, which was given entirely free, and work done by the private masseuse, for which fees were necessarily high. The masseuses had accordingly decided to start a massage clinic for people of limited means, who wished to pay but could not afford full fees, and, by the kindness of the Pleasance Trust, they had been allowed to start it in the Pleasance premises. The clinic would be self-supporting, and patients would, as a rule, be recommended by their own doctors, while the work would be done under medical supervision. The clinic would be open for patients three afternoons weekly from 3 to 7. The Rev. T. Ratcliffe Barnett, Ph.D., spoke of the close relation which would subsist between this clinic and the orthopaedic hospital that was to be built at Fairmilehead. He said that he had great sympathy with what was called "the middle wedge"—that is to say, people who could not afford expensive nursing homes, but who did not like to take everything for nothing.

Edinburgh Dental Hospital.

The annual dinner of the Edinburgh Dental Students' Society was held in the North British Station Hotel on January 24th, when Dr. A. Johnstone Brown presided over about 100 students and teachers of the school. In proposing the toast of "The Incorporated Dental Hospital and School," Dr. Drinkwater said he had always been impressed by the extraordinary development of the Dental Hospital in what might be described as half a lifetime. He remembered the institution occupying a flat in Cockburn Street, afterwards small premises in Lauriston Lane, and finally its transfer to Chambers Street, where at first it was situated in somewhat retired buildings. Since then it had come to the front in more senses than one, and now with its fine new building facing Chambers Street it was one of the best-equipped dental hospitals in the United Kingdom. This had been mainly due to the energy and ambition of the present dean of the school, Dr. William Guy. Dr. Guy, in reply, mentioned that his connexion with the Dental Hospital went back forty years, and in that period the dental profession had made a great general advance.

England and Wales.

The London County Council Hospitals Scheme.

THE General Hospitals Committee, a subcommittee of the Central Public Health Committee of the London County Council, has now been constituted. It consists of twenty members, five of whom are members of the medical profession—namely, Dr. C. W. Brook, Mr. H. L. Eason, Mr. Somerville Hastings, M.P., Dr. S. W. Jeger, and Dr. Adeline Roberts. The Special Hospitals Committee, consisting of twenty-one members, includes Dr. Stella Churchill, Dr. S. Monckton Copeman, and Dr. C. A. Fuller. It is stated that circumstances do not at the moment render it expedient to give full effect to the scheme recently approved by the Council for the appointment of hospital area subcommittees, and this part of the scheme has been deferred for not less than six months after April 1st. It is proposed, however, that some readjustment of staff arrangements should be made as a temporary measure. The primary effect of the postponement of the formation of the area subcommittees will be to concentrate the work in the General Hospitals Committee, and to bring to headquarters the proposed area medical staff which the Council had agreed should be set up to deal with the work connected with the district organization of general hospitals. This arrangement, it is considered, will have the advantage that, over the period during which the full operation of the scheme is suspended, the staff will work in close association with the principal medical officer in charge of the whole of the Poor Law work, and will be in close touch with all the developments during the difficult stages of transition and adjustment of the present year. The number of positions of senior medical officer in the public health department will temporarily be increased by three, which positions will be filled by officers selected from the existing central administrative medical staff. The Central Public Health Committee recommends as to two of the three (the other being in abeyance) that Dr. W. B. Knobel and Dr. Letitia Fairfield, divisional medical officers, should be granted temporary rank as senior medical officers.

Maudsley Hospital and the Central Pathological Laboratory.

In view of the fact that the work at the central pathological laboratory of the London mental hospitals service at Maudsley Hospital has increased largely during the last ten years, the Mental Hospitals Committee of the London County Council is proposing to add to the fixed staff of the laboratory a qualified medical assistant for research work, and also an assistant medical officer to effect liaison between the central laboratory and the mental hospitals. For the former position the basic remuneration suggested is £300 a year, which, with the present temporary additions, is equivalent to £423 a year. It is anticipated that such a position will attract young graduates who, after a few years, will leave research to take up some other branch of medicine. For the other position it is proposed that an assistant medical officer, selected from the more promising of the younger members of the medical staff of the mental hospitals service, should be seconded, full time, to the central pathological laboratory, the vacancy at the mental hospital being filled by the engagement of a locumtenent. It is stated that the number of routine examinations of specimens of body fluids and of post-mortem material carried out at the laboratory has risen from 313 in 1919 to over 8,000 a year, and is still increasing. During the past five or six years much instructional work on behalf of assistant medical officers and laboratory assistants from the mental hospitals has gone on at this central laboratory. This work is additional to duties in connexion with courses of instruction for the diploma in psychological medicine which are given at Maudsley Hospital under the supervision of the laboratory director. Two special departments of research have also been established, one for the investigation of the after-effects of encephalitis lethargica, and the other for the investigation of general paralysis. All this

additional work has limited the amount of time available for special research, and the director has to depend largely upon irregular aid from voluntary workers at the laboratory for assistance in experimental work undertaken by him personally.

Medical Cinematograph Display at the West London Hospital.

All the members of the medical profession in West London were invited by the West London Medico-Chirurgical Society to a special meeting at the West London Hospital on February 7th, when two cinematograph films of exceptional interest were shown, one being the well-known reconstruction of the experiments of Harvey and the other a film illustrating the conditioned reflexes, and prepared in Leningrad, partly in Professor Pavlov's laboratory. Dr. J. F. Halls Dally, president of the society, introduced the Harvey film, which has previously been shown on various occasions since its production under the auspices of the Royal College of Physicians in connexion with the celebration of the Harvey tercentenary. The captions of the film are chiefly extracts from Robert Willis's translation of Harvey's work, and the story opens with a representation of Harvey turning from the study of the treatises of Galen and Vesalius to experiment and dissection. The discovery of the phenomena of auricular and ventricular ejection, the passage of blood through the lungs, in particular the action of the pulmonary valves, and the general mechanism of the circulation are ingeniously depicted. In presenting the second film, Dr. G. M. J. Slot commented on the importance of the study of the conditioned reflexes in the development of neurology. The first part of the film showed the zoological gardens and playing fields of Leningrad to illustrate the behaviour of animals, children, and adults as indicating the mechanism of the brain. The usual expedients of the film studio were employed in order to demonstrate how various activities were built up by a series of reflexes or tracts in the nervous system. The film story then entered the region of elaborate physiological experiment, especially with frogs, indicating graphically the transmission of electrical and other impulses, and the reactions of the nervous system, even after the brain had been removed, to external irritation. The conditioned reflex, regarded for the purpose of this film as the unit of activity, was demonstrated in a manner of which textual description or even a succession of diagrams would be incapable. The captions of the film were originally in Russian, but they had been translated into English after the arrival of the film in this country. Another feature of the evening was the exhibition by Dr. Rickard W. Lloyd of a small painting of Harvey in his session, bearing the date 1647, which he believes, on n intrinsic evidence, to have been painted by Lely. unusual programme and the widespread invitation resulted in an excellent attendance, and the large out-patients' hall at the West London Hospital was almost filled.

Dr. C. J. Marsh and the Yeovil Hospital.

At the annual meeting of the Yeovil and District Hospital a special tribute was paid to the honorary secretary and treasurer, Dr. C. J. Marsh, who has for fifty years been actively associated with this institution; he was president of the Dorset and West Hants Branch of the British Medical Association in 1910. Dr. Marsh became a member of the hospital staff in 1880, when there were only four beds; there are now forty-six. Fifty years ago the number of in-patients for the whole year was fifty-eight; in 1929 the total number of patients admitted was no fewer than 731. The opening of the present hospital buildings in 1923, by the Prince of Wales, marked the turning-point between the old and the new institutions. In 1926 Dr. Marsh retired from his active work on the clinical staff, and his services were commemorated by the presentation of his bust in bronze; since 1924 he has been honorary secretary and treasurer of the hospital. In his annual report on this occasion both the receipts and the expenditure had risen considerably, but there was a credit balance of over £150. The annual subscriptions showed the largest increase on record, but contributions from villages had diminished. A striking feature of the report was the greater number of fees received for x-ray examinations; the new portable apparatus had proved a great boon. It was mentioned at the meeting that Dr. Marsh, in addition to his other work for the hospital, had developed more than 500 films during the year.

Correspondence.

EARLY JUVENILE RHEUMATISM.

SIR,—Dr. Carey Coombs and Dr. Reginald Miller have performed valuable service in calling attention, in the *British Medical Journal* of February 8th, to the insidious prodromal symptoms of acute rheumatism in children. The condition is of frequent occurrence among children living in the slum areas of large cities, but its true nature is only too rarely recognized; many patients who escape a false diagnosis of tuberculosis are simply labelled "anaemia" or "debility." Yet the treatment of these children is at least as important as the treatment of an obvious acute attack—possibly more so; I have no doubt that many cases of cardiac valvular disease in later years could be prevented, and the severity of others could be mitigated by rational treatment during this initial insidious stage.

The possibility of confusion of the early constitutional symptoms with those of tuberculosis and other conditions has been pointed out by Dr. Miller; to his admirable list of symptoms I would add vague abdominal pains, which appear to be a feature of some cases. I have seen acute rheumatism simulate appendicitis in one case; in two instances a diagnosis of "tuberculous abdominal glands", was made at the onset of acute rheumatism, and in one of these a later exacerbation of endocarditis was at first regarded as paratyphoid owing to the predominance of abdominal symptoms. Both the latter cases progressed unfavourably to a fatal pericarditis; a necropsy in one of them failed to reveal any intra-abdominal cause for the symptoms.

It is necessary, however, to go even further, and to point out that not all cases of genuine rheumatic infection ultimately develop a typical acute attack in one or other of its varied manifestations; on the contrary, certain cases remain insidious or "subacute" from beginning to end. The fact that, in a given case, these initial constitutional symptoms do not ultimately lead to an obvious acute attack of rheumatic arthritis, carditis, or chorea is not sufficient to refute a diagnosis of rheumatic infection. I have recently had the opportunity of following the development of mitral stenosis in such a case over a period of two years.

The boy never had a typical acute attack of endocarditis, arthritis, nor chorea, but he was never well, and never quite free from symptoms of one or other of the three. At times he was found to have a rather diffuse apex beat extending as far as the nipple line, with a faint apical systolic murmur, but the signs disappeared within twenty-four hours when he was confined to bed. At other times he was restless, with hyperactive reflexes, though choreiform movements were never observed; periodically he had vague pains in the limbs. For some days at a time he had an evening temperature of 99° F., with a pulse rate of about 100. Throughout, he had a poor appetite, was easily fatigued, and anaemic. In view of the ultimate development of a typically rheumatic valvular lesion there can be no doubt that he was suffering from a subacute or latent form of rheumatic infection.

Subacute cases of this nature are almost certainly responsible for many of the cases of mitral stenosis in adults who give no history of acute rheumatism, chorea, or other evident rheumatic manifestation; I have been unable to obtain a "rheumatic" history in some 20 per cent. of cases of mitral stenosis.

Much can be done in the treatment of these cases once they have been recognized. Restriction of activities in greater or less degree is necessary for all; in some, longer hours of sleep, with less violent exercise, will suffice, while others will require absolute confinement to bed for considerable periods. Each must be judged on its merits, and frequent examinations are essential. The parents should understand the necessity for informing the medical attendant of the occurrence of sore throats, "colds," pyrexial

attacks, or other suggestive symptoms. Many of the children are poorly nourished and in need of dietetic attention; the majority require treatment for their anaemia. The judicious use of salicylates—the exhibition of adequate doses at the proper time—may avert the more acute manifestations. Focal sepsis demands attention, particularly to the tonsils, but a word of warning is necessary, for much harm may result from an unnecessary tonsillectomy in a child with a cardiac infection. Where tonsillectomy is definitely indicated, it is important to choose the most suitable time, and to endeavour, first, to bring the child's general health to the highest possible level.—I am, etc.,

ALBERT A. FITZGERALD PEEL, D.M.,
February 8th. Electro-cardiographer, Victoria Infirmary, Glasgow.

RETENTION OF URINE.

SIR,—In the *British Medical Journal* of February 1st (p. 192) Mr. H. J. McCurrich gives an excellent summary of the treatment of retention of urine. His article is full of useful information and is eminently practical. There is, however, one piece of advice he gives which, if followed, may have disastrous consequences, as I know to my cost.

In speaking of suprapubic puncture in the treatment of impassable strictures, he says that "The bladder should be emptied slowly, or only partially." *Partial* emptying of a distended bladder by suprapubic puncture is, in my experience, a very dangerous proceeding. A house-surgeon of mine, who had been imbued with the idea that to empty completely a distended bladder entailed a great risk to the patient, half emptied the bladder by suprapubic puncture in a case of complete retention due to an impassable stricture. Twenty-four hours later I found the patient very seriously ill. After the trocar had been removed the bladder had continued to empty itself into the cellular tissues of the pelvis, and, as a result, serious pelvic cellulitis had developed. The patient was eventually saved with the help of suprapubic drainage and very free incision of the infiltrated tissues, but for two or three days his condition remained critical. If puncture is employed the bladder must be emptied very slowly, but must be completely emptied. Should complete emptying be contraindicated it is better to insert a Pesser catheter.

I point this out, not in a spirit of criticism, but because Mr. McCurrich's article is so excellent and so convincing that it would be dangerous to let a serious error pass unnoted.—I am, etc.,

London, W.1, Feb. 3rd. KENNETH WALKER.

THE CLASSIFICATION OF BRIGHT'S DISEASE.

SIR,—I was much impressed when reading your leading article on this subject (February 1st, p. 205) to find that the term "ischaemic nephritis" has made its debut. The fact that if the blood does not traverse the kidney properly a pathological change in the organ is induced is thus now expressly recognized. But, according to your leader, the author limits this term to conditions produced by changes in the vessels supplying the kidney—the glomeruli—with blood. In the classification there is not an "ischaemic nephritis" due to any other cause—for example, compression of the capillaries, caused, for instance, by a distension of the tubules (*plus* Bowman's capsules) reacting with the tension of the capsule of the whole kidney, and cured by incising that capsule. The lesions occurring in such a state as post-partum anuria seem not included in the category "ischaemic nephritis," but in that of "toxic nephritis."

Now apart from ascending surgical nephritis and that due to the tubercle bacillus—real inflammations—so-called "toxic nephritis" perhaps does not exist at all, chronic interstitial nephritis, the arterio-sclerotic kidney, and the kidney of essential hypertension being the only likely genuine examples. Certainly the changes occurring in the kidney during pregnancy and related with the clinical states called "toxaemias of pregnancy" are not due to a toxin of any sort. They are produced mechanically, and they are cured by mechanical means, as I showed in my paper of last year.[1] On the other hand, it is difficult to understand how a change in the blood supply to the kidney—even to the glomeruli—induced by a narrowing of the arterial path, however so caused, can occur, except as the result of a change in the blood—that is, by a toxaemia. But here not an "inflammation," but a "regression," is produced.

It would thus seem that there is something further to be said before finality on this matter is reached.—I am, etc.,

Rugby, Feb. 3rd. R. H. PARAMORE, F.R.C.S.

[1] Eclampsia and its Renal Lesion, *Journ. Obstet. and Gynaecol. of the British Empire*, 1929, xxxvi, 341.

PSYCHOGENIC PAIN.

SIR,—I have read with much interest the correspondence on this subject in the *Journal*. The impression I have gathered from it is that your correspondents seem at cross purposes; they wage a war about words, using the terms "psychogenic" and "physiogenic" with changing connotations. Whether centrally originated pain has at all been envisaged seems to me doubtful; but, if so, has it been classed as psychogenic or physiogenic?

To begin with, we have to be absolutely clear that pain is a psychical experience, pure and simple, and nothing else. That it has a neural basis—that is to say, that it is accompanied by (I should prefer to say that it is the subjective aspect of) an excitation of certain groups of cortical and subcortical neurones—is equally certain.[1] Without entering into the question of localization, let us call these neurone groups the "pain centre." The excitation of the pain centre, then, is the objective aspect of the pain experience. The pain centre may be stimulated in several ways: (1) by afferent impulses from the periphery (which includes the viscera, etc.); (2) by lesion in the centre itself[1]; (3) by impulses from other functioning parts of the brain, the subjective aspect of such functioning being a psychic experience. These psychic experiences arising through (1) and (2) I should be inclined to call physiogenic pain, while those caused through (3) psychogenic pain.

This last point, I believe, requires a little further elucidation. We speak—and we know that it exists—of psychogenic asthma, for example. A man is affected by certain grass pollen; he contracts hay fever and suffers from asthma. The experience is accompanied by the knowledge of the cause and the sight of the meadows with the grass in full bloom. The pollen is the exciting stimulus, and the sight of the grass meadows becomes the conditioned stimulus. The psychogenically originated asthma is the conditioned reflex which may possibly be elicited by the sight of a painting of a meadow in the absence of any pollen.

Do analogous cases in the field of pain experience exist? I do not know. Can the statement of an untrained person be taken as evidence? I should hesitate. Finally, it is most important to bear constantly in mind that the memory image of a pain is no more a pain experience than the memory image of St. Paul's Cathedral is the same as the visual experience while actually looking at the church. Another point likewise to be remembered is that a hallucination is an actual psychic experience. The patient who in delirium tremens sees rats that have no existence has nevertheless a visual sensory experience.—I am, etc.,

Shortlands, Feb. 8th. A. WOHLGEMUTH.

THE FUNCTION OF THE ASTHMATICAL REFLEX.

SIR,—In a letter in your issue of May 18th, 1929 (p. 930), I suggested that it was important to start a study of asthma by reading the physiological work of Professors Brodie and Dixon on this subject. Your kind compliance (July 13th, 1929, p. 68) with my request that you should publish a summary of this valuable but inaccessible document made it possible for everyone to discuss the matter in a scientific rather than an empirical manner.

Brodie and Dixon's experiments showed that asthma is a physiological reflex, chiefly activated by stimulation of the nasal mucous membrane; but they do not show the purpose it is intended to fulfil. Such well-defined reflexes are commonly directed towards a useful object: it would

therefore seem important to recognize the use of the asthmatical reflex, in order to appreciate the nature of such deviations from the normal as may be described as morbid.

By irritating the noses of asthmatics it is possible to cause lacrymation, sneezing, coughing, and, in some cases, asthma. The presence of asthma among these other well-known defensive reflexes suggests that asthma may itself be a defensive reflex, and this view is confirmed by further evidence. During gas attacks in France it was a common experience that, while many victims were overwhelmed, and their lungs damaged by a large dose of poison gas of an irritant nature, numbers who at the time suffered from severe dyspnoea and wheezing escaped with little or no injury. Spasm of the bronchial muscle was noted at the time, but, in the presence of a greater evil, was not recognized as asthma of the morbid type, and rightly so. Evidence more scientific was provided by those who, in studying the effect of gas inhalations on the lungs of dogs which were introduced into gas chambers, found that although some were overwhelmed by heavy dilutions, others, which were submitted to lesser dilutions, suffered only from dyspnoea and wheezing, which were relieved by injections of adrenaline.

Brodie and Dixon's experiments were performed upon normal dogs which were not suffering from any recognizable or stated metabolic or other disorder. Similarly, healthy individuals, whether human or animal, show bronchial spasm when in certain kinds of poisonous atmosphere. It is obvious that under such conditions the coughing or sneezing reflexes, which are invariably preceded or followed by a deep inspiration, would have no protective effect. But when, as in asthma, the bronchial muscle is contracted, the tidal air limited, and a layer of mucus secreted in the bronchial tubes, the protective syndrome is complete. It is obvious also that the nose is the first organ to recognize dangerous atmospheric conditions, and significant that the reflex is set in motion from the nasal mucous membrane. Brodie and Dixon found that the further back and the higher up on the nasal septum a stimulus was applied the more effective it was in producing bronchial spasm. This is synonymous with saying that it is most effective on the olfactory mucosa. It seems, therefore, self-evident that the asthmatical reflex is a normal defence against an atmosphere which can be recognized by the individual as being poisonous or harmful to the lungs. I am not referring to those deviations from the normal which are to be found in asthmatics.—I am, etc.,

London, W.1, Feb. 1st. H. MORTIMER WHARRY.

"TENNIS ELBOW."

SIR,—Before you apply the editorial closure, may I be permitted to attempt to draw into some sort of pattern the tangled threads of this discussion? I have the details of the original debate and the subsequent correspondence before me, and, although no two opinions agree, the condition really seems to me as capable of interpretation as regards etiology, pathology, and treatment as any other minor lesion, say, a strained back or a sprained ankle.

As Mr. Denis Browne points out in his excellent letter (January 11th, p. 89), one of the difficulties in reaching relative truth in the matter lies in the tennis expert's ignorance of anatomical details, and in the medical orthopaedic authority's ignorance of the mechanical details of the stroke. I had the opportunity of discussing tennis elbow recently with the man who has been, and perhaps still is, the greatest living tennis player. His opinion was brief and dogmatic. There are two forms, he told me: one, inflammation of the joint requiring operation; the other, in which the bones of the forearm are out of line, requiring an osteopath! The medical expert, on the other hand, even when he has personal knowledge of the condition, concludes that one variety—his variety—covers all. *Ex uno disce omnes*, he seems to say, when, in fact, *ex uno, disce unum*.

Let me show, briefly, by a personal observation, how tennis elbow originates and what lesions it may ultimately produce. Last week, in a local club tournament, I played an open single, and was beaten after 34 games; in the afternoon I played a handicap and won after 31 games. Each game represents some 6 or 8 rallies or more, each rally some 6 to 10 or more strokes. Thus, in the course of a few hours, I had struck my half share of 65 × 8 × 10 strokes—that is, some two or three thousand blows, involving about all the movements of which the fingers, wrist, elbow, and shoulder are capable. Needless to say that, being no longer a youngster, I suffered that evening from weakness and tenderness of my whole arm, with definite pain at certain strategic points—over the flexor and extensor muscles, over the radio-humeral joint, over the styloid process of the radius, and over the inner end of the carpus. Equally needless to say, a hot bath and a night's rest put matters right. Such is the first stage of so-called tennis elbow or, better, tennis arm. If toxaemia from teeth or tonsils or intestine is present, this stage may be prolonged or accentuated, and the opinions of Mr. Ross Smith and Dr. Alfred Jordan (January 4th, pp. 43, 44) and of Mr. Jenner Verrall (December 14th, 1929, p. 1109) will be confirmed. . . .

If a few days' or weeks' rest does not suffice to give relief, a visit to the skilled surgeon is required; Depending upon his personality and upon the clinical aspect of the particular case the verdict will be as follows —taking, perhaps, Surgeon Commander Edgar's advice (December 28th, p. 1219), and saying, as we make pressure on some special area; "Ah, I was afraid that might hurt you." (1) If pain is more or less centred over the radio-humeral joint it is that variety of tennis elbow so well described by Mr. W. H. Trethowan—possibly requiring open operation. (2) If the maximal pain is over the extensor carpi radialis longus, near its origin, then it may be that form of tennis elbow experienced, studied, and described by Mr. Denis Browne. (3) If the pain is limited to the "orbicular ligament" it is a case of tennis elbow due to ligamentous strain as described by Mr. Paul Bernard Roth (January 4th, p. 42). In other words, the original strain, at the basis of all degrees of this lesion, results in congestion and exudation and inflammation that may involve one or several of the tissues of the arm.

Mr. Blundell Bankart (January 25th, p. 170) refuses to admit any explanation other than his own, "a little greyish-red nodule about the size of a pin's point" under the common origin of the extensor muscles. (Surely he means a pin's head, at least?) He sweeps aside, as negligible, evidence found by other men of other conditions in what seem to them cases of tennis elbow. He speaks of four cases, and adds, *ex quattuor disce omnes*. In spite of his objection, the term tennis elbow or tennis arm will persist just because it fitly describes lesions at the base of which lie "various pathological conditions." That is proved by the discoveries made by Mr. Trethowan, Dr. Denis Browne, and himself—all skilled observers. If we adopt Mr. Bankart's view and sacrifice the term tennis elbow, then we must use some such clumsy and, in the opinion of many, inaccurate phrase as "traumatic hypo-condylar muscular rupture resulting in the formation of a minute cicatrix."

Mr. Bankart insists upon local anaesthesia because the lesion is so minute that it can be found "with certainty only by searching with a probe, when the patient exclaims, 'That's the spot.'" But if there were the least excess of local anaesthetic, there might be a risk of the minute spot being anaesthetized and undiscoverable. In the same way Mr. Trethowan insists on a tourniquet and a bloodless field, the effect of which might render difficult of appreciation the hyperaemia he states is present in the synovial fringe of the joint.

With regard to "cure"—that consummation devoutly to be wished—we know, alas! that the word is differently understood by the medical profession and by the public. The latter believe that our remedies "cure" colds, "cure" pneumonia, "cure" typhoid fever. The profession uses the word in its original Latin sense of "care." Our treatment takes care of these ailments. In the same way we may take care of tennis elbows by rest, warmth, electricity, massage, operation. No one method can be styled a cure, for even operation will sometimes leave the last state of that joint worse than the first.—I am, etc.,

Cannes, France, Jan. 27th. A. A. WARDEN, M.D.

LEAD POISONING FROM TAP WATER.

SIR,—In the *Journal* of February 1st (p. 216) Dr. Cooke very rightly drew attention to the danger of lead poisoning from tap water, and especially from hot-water taps. For many years I have been aware of this source of lead poisoning, and as medical officer of health for the urban district of Ramsbottom, which has a moorland water supply, I wrote the following sentences in my annual report for the year 1912.

"One feature to which I should like to draw attention is that when hot it (the water) has a plumbo-solvent action, and in houses having a hot-water system the water from the hot taps contains a considerable quantity of lead (presumably dissolved from the pipes) in solution. In private practice within the last six years I have met with about a dozen cases of lead poisoning of a more or less minor degree, apparently all traceable to the habit of using water from the hot taps for cooking purposes and for filling the kettle when in a hurry to make tea."

Since writing this I have met with many more such cases, one significant feature being that in most cases the patients were inmates of public houses. Recently two very marked cases came under my notice; the victims were a clergyman and his wife. It was found that the drinking water—the source of which is the local moorland and is a private supply—was heavily loaded with lead, having passed for 40 yards through a lead pipe between the cistern and the rectory in which they lived. In this instance the water from the cold taps contained a dangerous quantity of lead, and that from the hot taps very much more. My annual reports almost without exception reiterate this warning.—I am, etc.,

Ramsbottom, Lancs., Feb. 3rd. H. LAWRIE.

SANITATION ON THE RIVIERA.

SIR,—Your correspondent "Medicus" (February 1st, p. 218) traverses my statement that sewage is emptied on the foreshore, and says that the streams I have referred to are small streams coming from the hills behind Nice. I would not have made such serious statements without very careful inquiries beforehand. They are, I am sure, absolutely true, and your correspondent is misinformed. I made very careful inquiries from people who were interested in putting the best possible complexion on the sanitation of Nice, and they told me regretfully that it was impossible for anyone to deny that these were actual sewers. I had it also on good authority, as I stated in my first letter, that bathers had found faecal matter floating about in the neighbourhood of these drains. The president of the Syndicat d'Initiative de Nice practically admits the same thing to you in his letter when he says, "Only the sanitation of the sea may lend justification to some criticism, but in this matter also the municipal authorities are not inactive, and it is certain that they will bring about, in common with the other resorts on the Riviera, a complete and absolutely perfect sanitary system of the sea."

With regard to the statement that refuse is not conducted to the sea by the drains, I never suggested that it was; what I said was that I actually saw rubbish carts tipping refuse over the cliffs into the sea in the neighbourhood of Nice and elsewhere along the Riviera. With regard to the evidence of an offensive smell from the drains, no one would suggest that this smell is to be detected when the tide is in or on cold days, but I repeat my assertion that on warm evenings, with the tide out, another doctor and myself had to skirt round inland opposite each of these drains because of the smell.

My experience is, in almost every respect, widely different from that of "Medicus." It is possible that the new water supply may be a great improvement on the old, but it is to be hoped that too much reliance is not being placed on the action of the sun alone, as might possibly be inferred from the last paragraph of the president's letter. I am glad to learn that the authorities at Nice are making most vigorous efforts to secure for the city all the advantages of modern sanitary methods, but the average English medical man will hesitate to send his patients there for health cures until he has an assurance that the sewage is being dealt with otherwise than by being emptied on the foreshore.—I am, etc.,

London, W.1, Feb. 1st. R. H. ELLIOT, M.D., Lieutenant-Colonel I.M.S. (ret.).

SIR,—I stayed at Nice some year or so ago, in a quite good hotel, and found the drains in the annexed bathroom so bad that the smell came into the bedroom. The bath overflow pipe was led into the emptying pipe on the far side of the trap (if any), so that I had to cover the overflow grid with rubber plaster while having a bath. It was indeed doubtful whether there was an efficient trap to the bath-emptying pipe at all. Also the water-closet soil pipe leaked gas very badly. As a result the bathroom had to be shut off by the double doors whenever possible, and the window left wide open irrespective of the weather. The management admitted that the installation was not what it should be, but it appears very difficult to get intelligent work put into the plumbing in some places.

The remarks of your correspondents about the totally unnecessary noise of motor traffic are by no means exaggerated. Every vehicle, going in every direction, seems to delight in making the greatest possible amount of noise at every crossing. Not infrequently their Southern exuberance leads them to blow their horns to the "om, tiddley-om-pom: pom-pom" rhythm which used to be considered humorous here, and which apparently has not lost its freshness for them; but when you hear it blown for half a dozen streets before the musician reaches you, and for another half a dozen after he has passed, you are apt to yearn for the comparative peacefulness of a Mills bomb—suitably placed.—I am, etc.,

Leigh, Lancs., Feb. 3rd. JOSEPH JONES, M.D.

POLLUTION OF RIVERS.

SIR,—During the past three months the press has contained an exceptional and deplorable number of reports of serious pollutions of rivers, in many cases accompanied by the destruction of immense quantities of fish. It is a notable fact that most of these have occurred below beet sugar factories, and at just that period of the year when the beet is being received at the factories and converted. The claims of the managers of the factories that they are not responsible cannot therefore be accepted. The facts speak for themselves.

How great has been the injury may be illustrated by two or three examples:

River Witham.—Thirty miles of river polluted. Loss of fish estimated at hundreds of tons. Stench from the river described as "unendurable," so that men in mills and on works on the banks could not continue at work. Scum and froth reported to float on the edges of the stream eighteen inches to two feet deep. Great anxiety is felt that the valuable shell fisheries at the river mouth near Boston will be destroyed.

Rivers Ouse and Wissey.—Great destruction of fish reported. The decaying fish are stated by the medical officer to be polluting the local water supplies, which are dependent on the river. In many cases inhabitants and their cattle had to drink water which stank and was dangerous to health. Fears were expressed that an epidemic might break out.

River Nene.—Vast quantities of fish in the river reported destroyed and rotting. Peterborough Corporation collected and destroyed several cartloads, and the Fishery Board stated it would take twenty years to replace the loss. The bathing place had to be closed. Complaints were received that the stench made it impossible to live or work near the river, and great anxiety is felt as to the results of the pollution on supplies of drinking water.

The list could easily be multiplied. It is obvious that the loss to owners and occupiers along the banks of the streams affected must, in the aggregate, have been enormous, while a very large number of anglers, mostly working men, have been deprived of a very innocent and health-giving means of recreation. It is no less than a disaster, which is made the more deplorable as it was so unnecessary.

The beet sugar industry is being fostered by the Ministry of Agriculture and Fisheries, and has already received over £14,000,000 of the taxpayers' money in subsidies. Before the industry was set up the nature of the effluents from the processes to be adopted was known or readily ascertainable, and the pollution was remediable. Yet, despite the fact that the Ministry is also charged with the care of our fisheries, the factories were in most cases placed on non-tidal waters containing fisheries, where the pollution was likely to have the worst possible results; moreover, other processes of beet production which do not produce these immense quantities of poisonous effluent are known and in successful operation.

The whole discreditable episode points once more to the urgent need for improvement both in the law relating to river pollution and in its administration. Clearly it should be made a condition of all grants of public money, whether for fostering industries, improving roads, or constructing sewage works, that such moneys shall not be applied so as to pollute our rivers and, incidentally, injure the taxpayer who himself has to contribute to the subsidy. Equally urgent is the need to prevent factories being set up without adequate purification plants and sufficient space to enlarge such plants in proportion to any increase in the size of the factory and its output of noxious effluents.

The anglers of the country, numbering many hundreds of thousands, are at one on the subject. The Pure Rivers Society, which represents also all interests concerned in the purity of our rivers and inshore waters, is engaged on the drafting of a bill to be introduced into Parliament dealing with these and other necessary amendments in the law. It appeals to all men and women of good will to give their help and co-operation in a campaign which is essential if our rivers are to be saved from becoming open sewers.—I am, etc.,

1, Linco'n's Inn Fields, W.C.2, Feb. 6th.

T. W. GOMM,
Honorary Secretary, Pure Rivers Society.

TREATMENT OF RELAPSING FEVER.

SIR,—It has been brought to my notice frequently that many medical practitioners in tropical countries persist in using novarsenobenzol for the treatment of relapsing fever (known as "tick fever" in Central Africa). This is expensive, and is in no way better than the treatment which has been in use in the David Gordon Memorial Hospital since 1925—namely, the use of intramuscular injections of sodium potassium bismuth tartrate. This type of fever is very common on the Central African plateaux, and a cheap and easy method of cure is the more desirable. My observations on the two methods of treatment are as follows.

Novarsenobenzol brings the temperature down within twenty-four hours, but relapses are quite common, and two, or even three, injections of the drug may be required (especially in Europeans) before the patient is entirely free from symptoms. Moreover, intravenous injections are unpleasant.

Sodium potassium bismuth tartrate does not reduce the temperature so quickly—thirty-six hours is the average—but once it is down it remains down. Relapses are almost unknown. I am quite certain of this in regard to Africans, but not so certain about Europeans. The drug is given intramuscularly—a very easy procedure which can be performed by assistants. The dosage in use here is as follows. For an adult, two injections (on consecutive days); each injection consisting of 0.2 gram of the drug dissolved in 2 c.cm. sterile water. For a child, 2 to 10 years old, two injections on consecutive days; each injection consisting of 0.1 gram of the drug. For a baby under 2 years old one injection of 0.1 gram is sufficient.

I hope these notes may be of use to some of my fellow practitioners in the tropics.—I am, etc.,

Livingstonia, Nyasaland, Dec. 26th, 1929.

JOHN TODD.

DISPOSAL OF THE DEAD.

SIR,—Comparative study of the obituary columns of the papers of to-day with those of some thirty or forty years back reveals a great change in the minds of educated people concerning the disposal of their mortal remains. The material from which I have gathered the general trend of this change is a differential classification of the specific wishes of individuals expressed before their deaths, and subsequently printed in the obituary columns of the *Times* for the twelve months ending September 3rd, 1929, as to the obsequies to be observed in connexion with the interment of their dead bodies. Many of the injunctions thus set forth were found to be quite modern features, conspicuous by their absence from obituary insertions of Victorian days.

During the year mentioned there were 16,338 death announcements in the *Times*, of which 14,116, or 86.4 per cent., pertained to ordinary conventional burials. The remaining 2,222 cases, or 13.6 per cent., referred to special disposals of remains, and from these the present analysis has been made. The change in public opinnon, as indicated by the classified results, lies mainly in an increased tendency towards—

1. Replacement of floral decorations at funerals by gifts of flowers to hospitals or by donations to charities instead of purchased wreaths, etc. There were 1,555 requests (9.5 per cent.) for "no flowers," and 32 (0.2 per cent.) for alternative donations to hospitals and other charities.

2. Discontinuance of such outward and visible signs of mourning as black habiliments and corresponding paraphernalia. Modern thought is demanding a less depressing effect of death upon the living, and is beginning to recognize the reality of a psychological basis for the old adage, "One funeral leads to another." Three hundred and forty-three requests (2.1 per cent.) were made for "no mourning."

3. Private funerals or, where public, requests that no ladies should attend. Seventeen (0.1 per cent.) persons desired the former, and 11 (0.06 per cent.) the latter.

4. Cremation instead of ordinary burial. The relatively rapid rise of this hygienic method of disposal is evidenced by the fact that in 1928 cremations in Great Britain totalled 3,436, a figure exceeding that for 1927 by 5.24 per cent., and representing an increase of nearly 30 per cent. over the average for the preceding five years. During the year examined there were 739 cremation announcements in the *Times*, a figure bringing the total for this country, since the introduction of the system by Sir Henry Thompson, to well over 47,500. So steadily, indeed, is this method of disposal increasing in the British Isles that, in addition to the already existing twenty crematoriums, the erection of further ones is being considered by various local authorities.

Contrasted with earth burial the benefits of cremation are so many and, indeed, so obvious, that it is a puzzle why the system does not advance with even greater rapidity than is the case. Undoubtedly general adoption is checked by the higher cost of cremation as compared with that of ordinary burial, but there is, I think, a weightier and more complex factor militating against common use. "The greatest obstacle would appear to be" (I quote from the *British Medical Journal* of a few months back) "a widespread reluctance to think of the matter at all. Many persons, it is true, are prepared to discuss the desirability of cremation in the abstract; some will even discuss it in concrete terms so long as present company is excepted. It is, however, a big step from an academic acquiescence in cremation to a willingness and a capacity to leave explicit instructions about the disposal of one's own dead body, a bigger step than most people are at present prepared to take."

In cremation the constituent elements of the body, through the cleanly agency of fire, the regenerative mechanism of glorious Apollo, are harmlessly and speedily restored into Nature's currency instead of such process being spread over many years through the mediation of saprogenic anaerobic micro-organisms, a process not merely intrinsically repellent, but one fraught with danger to the living, a danger, moreover, that must necessarily increase in proportion to the ever-increasing congestion of cemeteries.

The one argument of weight against the incineration of human remains is the so-called "crime argument," but the regulations governing cremation have been so carefully framed with a view to this possible contingency that, as Sir Henry Thompson once said, "A crematorium is the last place to which a murderer would bring his victim." It is a most significant fact that, out of the odd 48,000 cremations already conducted in Great Britain, not one has given rise to subsequent question as to the cause of death. Nevertheless, to make assurance doubly sure, certain additional precautionary measures suggested by Dr. Ernest Cook might well be incorporated in the existing regulations. He would disallow cremation in cases where death is not obviously a result either of accident or of

some well-known disease, the effects of which upon the human body are thoroughly familiar to the medical profession. He makes the further suggestion that the authorities might with advantage follow some line resembling that practised under the Food and Drugs Act, wherein the article that is suspect is divided into three parts, each duly labelled and sealed. One part is handed to the vendor, a second part is delivered to the public analyst, a third part being retained for corroborative analysis in case of dispute. Such procedure would render possible, should occasion arise, three separate and independent expert scientific opinions. These suggestions carry the greatest weight and are deserving of serious consideration in that they are made by a writer with forty years' expert analytical work behind him.

Other expressed wishes of interest included 11 "to be buried at sea"; 4 "*no* memorial service"; and 2 that there should be "no tears."

Taken in their entirety the various wishes analysed afford striking evidence of the change educated public opinion is undergoing in regard to this vital question. The next thirty years will, I think, witness further progress in such opinions, an advance many to-day would call revolutionary. Those who evince a desire to be cremated rather than interred by ordinary burial give proof of a personal concern to benefit, even though this be indirectly and passively, the communal hygiene.—I am, etc.,

CHARLES M. BEADNELL,
Surgeon Rear-Admiral.

Ringwood, Hants, Feb. 4th.

ANAESTHESIA FOR SHORT OPERATIONS ON CHILDREN.

SIR,—I have been much interested in the letters in your correspondence columns from Dr. Harold Sington, Dr. Beresford Kingsford, and Dr. Langton Hewer. I quite agree that closed ethyl chloride is an admirable anaesthetic for children, especially in dental work; but my own experience of it is that an occasional case gives rise to some anxiety by developing signs of syncope in the early stages of the anaesthesia. Another cause for my objection to this type of anaesthetic is the spasm of the masseters which so commonly occurs. In my opinion both these drawbacks are completely overcome by combining oxygen with the ethyl chloride. I agree with Dr. Beresford Kingsford that when oxygen is used the induction period is slightly prolonged, but this is only a matter of a few seconds, and is more than compensated for by the extra period of anaesthesia.—I am, etc.,

H. MARCUS BIRD,
Honorary Anaesthetist, West Suffolk Hospital.

Bury St. Edmunds, Feb 8th.

TONSILLECTOMY OR RADIOTHERAPY.

SIR,—The letter of Dr. Douglas Webster is of great interest, as indicating a line of treatment for some cases of tonsillar enlargement. There is a definite place in laryngology for the treatment of enlarged tonsils by methods other than surgical ablation. This is particularly indicated in those cases of what might be termed symptomless enlargement of the tonsils. These cases confront the throat surgeon after the attention of the patient has been drawn to the condition by the personal medical attendant, the school doctor, or the doctor attached to the place of occupation.

No history can be elicited of symptoms referable to the tonsil, no rheumatic condition is present, nor can cervical adenitis be detected. As a rule the school or works doctor is in favour of surgical removal on the principle that "prevention is better than cure." Were tonsillectomy entirely devoid of risk, there might be some justification for this attitude.

This type of tonsillar enlargement is amenable to treatment with radium. Lymphoid tissue reacts specifically to radium emanations, and the tonsil tissue is no exception to this rule. Under local anaesthesia the radium needle is embedded in the substance of the tonsillar tissue and retained *in situ* for an adequate exposure—for example, a needle containing 20 mg. of radium element for, say, thirty hours. As this method of treatment requires the active co-operation of the patient it is inapplicable to children, who would pull the needle out.

While the method is suitable for the class of case mentioned, it must be remembered that by producing atrophy of the tonsil with radium it is not possible to prevent the tonsil from becoming subsequently the seat of any disease this organ is heir to.—I am, etc.,

N. ASHERSON.

London, W.1, Feb. 1st.

A FATAL CASE OF VARIOLA MINOR.

SIR,—A death from small-pox has occurred in Leicester, and as this is the first for over a quarter of a century (the last death having occurred in June, 1904) it calls for some comment. The victim was a weakly baby, bottle fed, the youngest of a large family, who was infected by an overlooked case in the family within a few days of birth. The child was taken ill on January 13th; the eruption appeared on the 15th, and the child was admitted to hospital, together with its mother and elder brother, both suffering from the disease, on the 18th. The child was then in an obviously serious condition. There was a fairly abundant rash, and the child had been refusing food and suffering from vomiting and diarrhoea for the last few days. It died the day after admission.

This case illustrates what is now well recognized—namely, that variola minor, although ordinarily a non-fatal disease, may occasionally, like varicella and other non-fatal diseases, prove fatal when it occurs in very young infants.—I am, etc.,

C. KILLICK MILLARD,
Medical Officer of Health, City of Leicester.

February 6th.

TRAINING IN MIDWIFERY.

SIR,—It seems to me that the article by Mr. Donald Roy in your issue of February 1st (p. 212) needs only to be read to be approved. The system of teaching students and midwives together has been the practice of the Rotunda Hospital for probably a century.—I am, etc.,

BETHEL SOLOMONS,
Master, Rotunda Hospital.

Dublin, Feb. 5th.

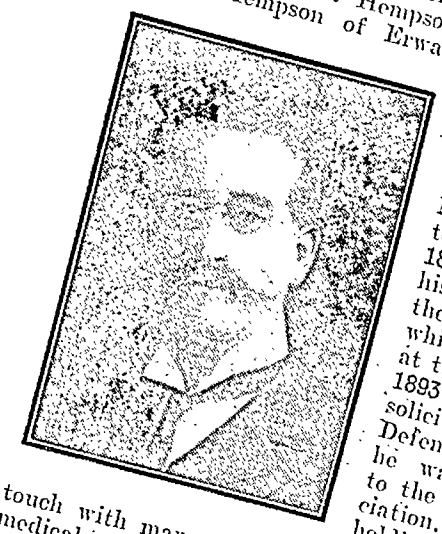
PAIN IN THE ILIAC FOSSA.

SIR,—Professor John Fraser's lecture on pain in the iliac fossa in the *Journal* of January 18th (p. 97) recalls to my mind the "via dolorosa," which I had to tread with weary feet for more than five years, before the cause, a renal calculus, was recognized and removed. Fortunately it was the left side which was affected; otherwise, I feel sure I should have been subjected to the "radical exclusion" method of arriving at a diagnosis.

My one and only symptom was a constant, boring ache, situated deep in the iliac fossa. It was quite localized, and never varied in position nor radiated in any direction. Its intensity varied from time to time, but, during the whole period, I was never free from it. As no local lesion could be found to account for it, I was variously diagnosed as suffering from "irritable colon," "neuralgia of the intestine," and that well-worn cloak of ignorance "neurasthenia." A point of interest to me was that when ureteral catheters were passed and the point of each hit the kidney (or its pelvis) I felt a sharp pain in the corresponding iliac fossa in exactly the same position as my former pain.

I should like to know if this is a very unusual position for the pain in a case of renal calculus, because I can find little reference to it in any literature that I have been able to get hold of. That may be the reason why it took so long to diagnose the cause of the trouble in my case, and the possibility that someone else may be travelling the same painful road as I did has prompted me to relate my personal experience.—I am, etc.,

M.B., CH.B.



January 27th.

Obituary.

WILLIAM ERNEST HEMPSON,

Solicitor to the British Medical Association, 1900–1928.

WE have to record with much regret the death at Tunbridge Wells, on February 6th, of Mr. W. E. Hempson, who was for nearly thirty years the trusted legal adviser of the British Medical Association.

William Ernest Hempson, one of the sons of the late J. A. Hempson of Erwarton Hall, near Ipswich, was educated at Ipswich Grammar School. He was admitted a solicitor in September, 1880, at the age of 21, and for a time was associated with Messrs. Freshfields, solicitors to the Bank of England. In 1890 he started practice on his own account, and founded the firm of "Hempsons," of which he was senior partner at the time of his death. In 1893 he was appointed solicitor to the Medical Defence Union, and in 1900 he was appointed solicitor to the British Medical Association. In consequence of holding these appointments he was brought into close touch with many members of the medical profession and medical societies throughout his active professional life.

Mr. Hempson was always an indefatigable worker. As a result of overwork during the war years, when his sons and many members of his office staff were away on active service, he was advised in the year 1919 that he must reduce his activities. He accordingly ceased to take part in the general practice of his firm from the year 1920, but he continued to advise the British Medical Association until the year 1928, when he finally relinquished the personal appointment of solicitor to the Association, and his firm (of which his son Mr. Oswald A. Hempson now becomes the senior partner) were appointed in his place.

In recognition of his many years of work on behalf of the Association he was elected an honorary member at the time of his retirement, a distinction of which he was extremely proud. Three years ago he placed at the disposal of the Council, as a mark of esteem for the Association and appreciation of his happy relations with it, a sum of money to be awarded as a prize for the best essay on some phase or branch of public health.

For many years Mr. Hempson was intimately associated with the Medical Sickness, Annuity, and Life Assurance Society, Limited. Since 1921 he had lived at Tunbridge Wells, where he played an increasingly active and useful part in local affairs. For the past seven years he had been a valued member of the town council, and served on many committees, including the Health Committee, of which he was chairman. His enthusiasm for gardening led to his election as president of the Tunbridge Wells Horticultural Society, and he was a keen supporter of all local athletic clubs.

At the funeral service on February 10th, in Rusthall Church, the Council of the British Medical Association was represented by Dr. H. B. Brackenbury, Chairman of Council, and Dr. Alfred Cox, Medical Secretary. The Tunbridge Wells Division was represented by Dr. F. T. C. Linton (chairman), Dr. Claude Wilson, and Dr. E. A. Starling. Dr. Victor Jaynes represented the Medical Defence Union. There was a very large attendance at the church service, in which the municipal and hospital authorities, and the legal and medical professions were well represented.

MR. E. B. TURNER, F.R.C.S., writes: W. E. Hempson was above all things "a B.M.A. man." The interests and honour of the Association were predominant with him, and he was at any moment keen and eager to give of his very best in its service. His advice was wise in all cases, and by following it many pitfalls in difficult and uncertain times were avoided. His presence at Council and Representative Meetings was always looked forward to and appreciated by those of us who knew him well. With the saving grace of humour, and a ready and flashing wit, he was a delightful companion when "off duty." Without great eloquence, he was wonderfully clear and impressive whenever he had occasion to speak, and no one who heard him could ever go away without an exceedingly clear understanding of the subject, however involved and intricate it may have been, on which he had been giving advice and enlightenment. He was full of experiences, and as a narrator both of facts and fancies unequalled. The Association, during the entire period of his connexion with it, had a whole-hearted friend as well as a wise counsellor, and to those of us who knew him well his memory will ever be present, and the recollection of his many qualities enduring.

THE MEDICAL SECRETARY writes:

The death of W. E. Hempson is a sad landmark in the history of the British Medical Association for old hands like myself. My acquaintance with him began just after he had been appointed solicitor to the Association. Sir (then Mr.) Victor Horsley, who had been deeply impressed with Mr. Hempson's work as solicitor for the Medical Defence Union, did much to secure his appointment to the Association. I saw a good deal of him in connexion with the work of the Constitution Committee of 1900. Mr. Hempson was then in the prime of his professional career, and nobody could have taken a keener professional interest than he did in the delicate work which had to be done in the formulation of the new constitution and bringing it into operation, and in which he and Dr. Smith Whitaker, then Medical Secretary, shared a very congenial task. And I remember particularly very strenuous work of his in connexion with the proposed Royal Charter, which unfortunately did not materialize. But all through his professional connexion with the Association he gave to it loyal and devoted service, which was by no means limited by merely professional considerations. He loved the Association and was never happier than when he could be of service to it. There was no member of the Association who looked forward more gladly than he did to the Annual Meetings, where he was a prominent and very popular figure. When he retired from the solicitorship he did so with great regret. I had many letters from him at the time which showed that he felt the parting very keenly, but the severance was mitigated by the knowledge that the connexion was to be continued in his firm. In a letter dated October 12th, 1928 (referring to the fact that the firm had been appointed solicitors and not any person by name), he said: "I rather felt and almost hoped that my own appointment, which was so essentially personal, might stand on its own plane, and under present proposed circumstances it will. . . . Although a lawyer I am not without sentiment, a confession which might possibly inspire you with mirth, but true confession whitens the soul, and I do not mind saying that the Association has always been to me something much more than a mere professional client." He was immensely pleased when the Council made him an honorary member of the Association.

He kept a keen eye on the progress of the Association, and read his *Journal* assiduously, as frequent letters showed, right up to the last. When Sir Jenner Verrall died he wrote me alluding to his long friendship with him, and went on to say: "For his active brain and ready speech he will long be remembered amongst us, and the profession owe him much for his zeal and devotion to their interests. There were a 'Big Four' in Macdonald [for whom he had a strong affection], Bolam, Verrall, and Brackenbury. The privilege of knowing them as intimately as I have done has added much to the pleasure of professional life."

His last letter, only a few weeks ago, asked for my advice with regard to some questions connected with the hospital at Tunbridge Wells, on the Board of which he had become active. After his retirement he devoted a great deal of time to public work as a town councillor and in other ways, and might, I understand, have been mayor of Tunbridge Wells had he so desired, but he was restrained by the fear that his wife's health would not be

equal to the duties which would fall on her. He devoted himself particularly to public health matters, in which his knowledge of Association work helped him, as he said, very considerably. He was a man of strong family affections, and I never felt sure whether he was more proud that one of his sons was in his own profession and would continue the connexion with the British Medical Association and the Medical Defence Union, or of the fact that another son was a rising member of the medical profession. He was a very good friend, genial, sincere, always ready to do a good turn at the expense of his own convenience, and many of us will remember him, as I shall do, as a devoted and sagacious servant of our Association and an able, upright, and highly respected member of his own profession. The numerous members of the Association who know Mrs. Hempson, always a welcome visitor to the Annual Meeting, will join in offering sympathy to her and her family.

Dr. JAMES NEAL, general secretary of the Medical Defence Union, writes:

By the death of W. E. Hempson the medical profession loses a wise counsellor and a devoted friend. Few men have done more for the medical profession as a whole or for so many of its individual members. As legal adviser to the Medical Defence Union for upwards of twenty-five years he acquired a unique experience of the difficulties with which medical practitioners are liable to be confronted, and his vigorous, skilful, and usually successful handling of the many cases entrusted to him will be remembered with gratitude by all those concerned. In the early days of the union many important questions of principle in medical defence were decided with the help of his expert advice and sound judgement, and hold good to-day. His annual summary of the legal work of the union, published with the annual report of the council, was always interesting and instructive, and aptly illustrated the zeal and untiring energy with which he so successfully upheld the rights of the members. It was my privilege to work in close association with Mr. Hempson for a number of years, and I gladly take this opportunity of paying my humble tribute to his high character. He possessed lofty ethical ideals, inspiriting enthusiasm, and sound common sense. All his work was characterized by most painstaking thoroughness. His own delight when he brought a difficult case to a successful conclusion was positively delicious. He never forgot an old friend, and his bright, cheery disposition always made him welcome at medical meetings. As a lawyer he was always respected, but I think those who knew him best will desire to cherish with affection the memory of a kindly friend and a courteous gentleman.

[The photograph reproduced is by Elliott and Fry, London.]

EDGAR RALPH DIMSEY, D.S.O.,

Surgeon Rear-Admiral R.N.(Ret.).

SURGEON REAR-ADMIRAL E. R. DIMSEY, who died suddenly on February 5th, was the son of D. G. Dimsey, an Admiralty official, and spent all his professional life in the silent service, and certainly, therefore, never sought a place in the limelight. He was an extremely able clinician, a charming personality endowed with much kindly humanity, which prevented him from taking himself seriously. Most considerate and generous to his subordinates, he was quite fearless and forgetful of his own interests in standing up for what he thought right. From August, 1914, to 1916, when many civilians passed through the Royal Naval Hospital, Haslar, as temporary surgeons and surgeon probationers, R.N., he was deputy surgeon-general in charge of the medical side of the hospital, and many of those who were cordially welcomed to this new experience in perhaps the most interesting time of their lives will hear with real sorrow of the death of one who helped them so genially. Born in 1861, he was educated medically at the Middlesex Hospital, and obtained the M.R.C.S. and L.R.C.P. diplomas in 1883. Entering the navy in that year, he attained the rank of surgeon rear-admiral on April 22nd, 1918, and retired in 1920. As staff surgeon of H.M.S. *Phœbe* he served in the punitive expedition commanded by Rear-Admiral Ranson, C.B., which was landed from the squadron to punish the King of Benin for the massacre of a political expedition in 1897, ending in the capture of Benin city on February 18th, 1897. He was mentioned in dispatches, and received the Africa general service medal, with a clasp for Benin, and also the D.S.O.

In 1918 he was promoted to surgeon rear-admiral, and after serving as final medical examining officer at Great Scotland Yard for naval recruiting during 1919, he was placed on the retired list in 1920. Happy in a love of literature and gardening, he lived a placid ten years at Burford, in Oxfordshire, with his family, and leaves a pleasant memory behind him.

H. R.

The unexpected death has taken place, at his residence in Merrion Square, Dublin, of Dr. FRANK J. KENNEDY CAHILL, who was a well-known practising physician in that city. The son of the late Dr. Mark Cahill, who was also a well-known figure in Dublin social and medical life, Dr. Cahill, after taking his medical degree, started in dispensary practice in Dundrum, co. Dublin, where he remained for some years. Subsequently he decided to study for a special branch of the medical profession, and to this end went to Boston, Massachusetts, where he studied under Professor Hemmiter, a leading authority on disorders of the stomach. Dr. Cahill, on his return to Dublin, secured an extensive private practice, and came to the front rank of the profession in the city. He was consulting physician to the Royal National Hospital for Consumption, and examiner in medical jurisprudence at the Apothecaries Hall, Dublin. He was a Fellow of the Royal Academy of Medicine, Ireland, and also of the Royal Institute of Public Health. For several years he served on the committee of management of the Dublin Sanitary Association. In 1907 he was elected a Fellow of the Royal College of Surgeons, Ireland. Dr. Cahill took a deep interest in the various meetings of the Royal Academy of Medicine in Ireland and of the clinical clubs in the city. He was a prominent member of the Arts Club, and was keenly interested in the Drama League and the Abbey Theatre, and had been for many years a member of the British Medical Association.

Professor JOHN ORCHARD TODD, M.D., who died last October in Winnipeg, was one of the leading practitioners of that town. He was born in London, Ontario, and received his medical education at the Manitoba Medical College, where he graduated in 1890. He was appointed professor of practical anatomy in the University of Manitoba, and later, after post-graduate study at St. Thomas's Hospital (London), Edinburgh, Johns Hopkins University, and New York, he was appointed professor of surgery in Manitoba. He was also gynæcologist, and later surgeon, to the Winnipeg General Hospital, and when he retired from active teaching he was appointed emeritus professor of surgery in the University of Manitoba. He served for two years in France during the war, and on his return to Winnipeg became chairman of the staff of the Victoria Hospital.

The following well-known foreign medical men have recently died: Professor RADZIEJOWICZ, an eminent Polish psychiatrist; Dr. CHARLES SOULIGOUX, a prominent Paris surgeon, aged 64; Dr. RAOUL ROBERT BAYEUX, author of a well-known work on diphtheria and intubation published in 1899, aged 58; Dr. DUBOUÉ, a Bordeaux physician; Dr. JULIUS ELISCHER, professor of roentgenology at Debreczen, aged 54; Dr. LÉOPOLD DÉLAEY, editor of *Le Scalpel*, and Commander of the Order of the Crown of Belgium, aged 76; Dr. VAN DER VALK, professor of dermatology and venereology at Groningen; and Dr. DE BOISSIÈRE, radiologist at Havre, as a result of radio-dermatitis, aged 55.

The Services.

NAVAL MEDICAL COMPASSIONATE FUND.

AT the quarterly meeting of the directors of the Naval Medical Compassionate Fund, on January 22nd, with Surgeon Vice-Admiral Arthur Gaskell, C.B., Medical Director-General of the Navy in the chair, the sum of £120 was distributed among the several applicants.

TERRITORIAL DECORATION.

THE King has conferred the Territorial Decoration upon the following officers of the Royal Army Medical Corps (Territorial Army), under the terms of the Royal Warrant of October 13th, 1920: Lieut.-Colonel G. H. R. Gibson, D.S.O., and Majors A. M. Johnson, *M.C.*, C. A. Webster, and J. A. C. Scott, *M.C.*

DEATHS IN THE SERVICES.

Lieut.-Colonel George Harrison Younge, R.A.M.C. (ret.), late of Oldtown, Rathdowney, Queen's County, Ireland, died at Clacton-on-Sea on January 2nd, aged 72. He was born on September 19th, 1857, was educated in the school of the Royal College of Surgeons, Ireland, and took the L.R.C.S.I. and L.K.Q.C.P. in 1879, also subsequently the F.R.C.S.I. in 1890. Entering the army as surgeon on July 30th, 1881, he attained the rank of lieutenant-colonel after twenty years' service, and retired shortly afterwards, on October 30th, 1901. He served in the South African war in 1900-1, when he took part in the relief of Ladysmith, including the actions at Colenso, Spion Kop, Vaal Krantz, Tugela Heights, and Pieter's Hill, and in operations in the Transvaal, Orange River Colony, and Cape Colony, was mentioned in dispatches in the *London Gazette* of February 8th, 1901, and received the Queen's medal with five clasps. He was also employed during the recent great war from April 15th, 1915.

Lieut.-Colonel Julian Carrington Carter Smith, O.B.E., Bengal Medical Service (ret.), died suddenly in Edinburgh, on December 19th, 1929, aged 75. He was born at Agra on August 7th, 1854, and was educated at Edinburgh, where he graduated as M.B. and C.M. in 1878. Entering the I.M.S. as surgeon on March 31st, 1879, he became lieutenant-colonel after twenty years' service, and retired on August 7th, 1909. Most of his service was passed in civil employ in the North-West, now the United Provinces. He served in the Afghan war of 1879-80, receiving the medal, and in the Burmese campaign in 1886-88, when he took part in the operations of the 6th Brigade, receiving the frontier medal with two clasps. He also rejoined for service during the war of 1914-18, and for his services received the O.B.E. on June 3rd, 1919.

Medico-Legal.

INSANITY PLEA IN MURDER TRIAL.

ON February 3rd the Court of Criminal Appeal (Mr. Justice Talbot, Mr. Justice Charles, and Mr. Justice Humphreys) dismissed the appeal of James Achew, who had been sentenced to death by Mr. Justice Avory, at the Central Criminal Court, on January 17th, for the murder of a woman with whom he had been living in Bayswater. The defence was that, at the time when he murdered the woman by cutting her throat, and then cut his own throat and put his head in a gas oven, the prisoner was insane. Mr. S. T. T. James, on behalf of the appellant, argued that on the evidence, medical and other, given at the trial, the only possible verdict which the jury could properly have returned was one of "Guilty, but insane." He asked the Court to exercise its powers by substituting that verdict for the verdict of "Guilty." Mr. Eustace Fulton was not called on to argue for the Crown. For the following account of the judgement dismissing the appeal we are indebted to the *Times* law report, published on February 4th.

Judgment Dismissing Appeal.

Mr. Justice Talbot said that the only question at the trial was whether at the time when the act was committed the man was or was not insane in the sense in which that word was used in law. A good deal of evidence on that question was called at the trial. There was the evidence of three people who spoke to the general demeanour of the prisoner as it appeared to the ordinary observer; and that of three medical witnesses, two for the Crown and one for the defence. No doubt on that evidence the jury might have found that the man was insane, but the question for the Court of Criminal Appeal was whether the jury were bound to find that verdict. After reviewing the medical evidence given at the trial, his lordship said that there was the sharpest difference between what medical men, and perhaps ordinary men, called insanity and the legal definition of insanity such as to justify a verdict of "Guilty, but insane." On the legal definition there was a definite ruling, which bound both the judge at the trial and the Court of Criminal Appeal.

His lordship, having read the fourth answer of the judges in M'Naghten's case, said that the application of that rule to the present case was quite clear. The prisoner had an insane delusion that the murdered woman was unfaithful to him, and so persistently unfaithful that, if she had really done the things which he suspected, she would have been a most abandoned woman. There was, in fact, no ground even for rational suspicion. But, assuming the dead woman had done all that the appellant insanely believed her to have done, it needed no statement that that did not justify a husband, or any other man, in putting an end to her life.

It appeared to the Court clear beyond all question that the appeal must be refused. That judgement, of course, could in no way affect any action which the Home Secretary, applying different considerations, might think fit to take.

JOINER MASQUERADES AS DOCTOR.

A WALTHAMSTOW joiner, Hugh McKay Rankin, was sentenced at Liverpool Assizes, on February 1st, to twenty-one months' hard labour, having been convicted of obtaining money by falsely pretending to be a medical practitioner. It was stated in evidence that in 1915 Rankin returned to this country from Canada, where he was said to have acted as a groom to a medical student; he then negotiated with a practitioner in East Ham to take over his practice, but failed to produce his diplomas when asked for them by the local Insurance Committee. Between February, 1916, and July, 1917, he made four voyages as ship surgeon, producing a diploma for inspection. His certificates of discharge from the ship were marked "Very good." Subsequently he undertook a locumtenency for a Glasgow practitioner, and was said to have performed the duties satisfactorily. In 1917 he was convicted of posing as a medical practitioner. Three years later he announced that he had a certain cure for cancer, and having obtained money to assist him in "research" was exposed and sent to prison. He then proceeded to the United States, whence he was sent back to Glasgow in 1925 after having been convicted of fraudulently giving himself out as a doctor. A year ago, in Cheshire, he masqueraded again as a medical practitioner, and became engaged to two or three women, from one of whom he obtained money by producing documents purporting to prove that he was a man of substantial standing.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

AT a congregation held on February 9th the following medical degrees were conferred:

M.B., B.CHIR.—G. N. Wood.
B.CHIR.—J. R. Peacock, S. R. Matthews.

UNIVERSITY OF LONDON.

MR. H. L. EASON, C.B., C.M.G., M.D., M.S., has been reappointed to represent the University on the General Medical Council.

Dr. W. W. Jameson, Professor of Public Health, has been appointed a representative to the Royal Sanitary Institute Congress at Margate in June next.

The William Julius Mickle Fellowship for 1930 has been awarded to Dr. H. A. Harris, Assistant Professor of Anatomy at University College, London, in respect of research during the past five years upon problems of growth in man and animals.

A diploma in public health for external students has been established.

UNIVERSITY OF DUBLIN.

SCHOOL OF PHYSIC, TRINITY COLLEGE.

THE diploma in gynaecology and obstetrics has been awarded to Dr. C. B. Teck.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

A MEETING of the Royal College of Physicians of Edinburgh was held on February 4th, when the President, Sir Norman Walker, was in the chair. Dr. Roy Mackenzie Stewart (Herts) and Dr. William Malcolm McAlister (Edinburgh) were introduced and took their seats as Fellows of the College. Dr. John Henry Douglas Webster (London), Dr. Arthur Oliver Gray (London), Dr. David Pieter Marais (South Africa), Dr. Sydney Watson Smith (Bournemouth), and Dr. James Kirkwood Slater (Edinburgh) were elected Fellows of the College.

Dr. David Rorie, D.S.O., was appointed Dr. Alexander Black Lecturer for 1930.

The College arranged to send a message of congratulation to the Royal College of Physicians and Surgeons of Canada on its creation.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons spent three days this week in committee on the Coal Mines Bill. For Wednesday a debate was arranged on rating in relation to housing, and the first order for Friday was a Local Authorities (Enabling) Bill to extend the powers of local authorities. A Protection of Dogs Bill was down as third order for Friday, but was unlikely to be reached.

The Government hopes to give Monday, February 17th, for the second reading of the Mental Treatment Bill in the House of Commons. On February 11th Mr. Greenwood met members of the Labour party at the House of Commons and explained the bill to them. His statement was favourably received, but some Labour members expressed a desire to have the Board of Control more closely under the Minister of Health. It was suggested that to ensure this "may" should be changed to "shall" at certain points in the bill. Mr. Greenwood promised to consider the suggestions.

The Parliamentary Medical Committee met at the House on February 11th, Dr. Salter presiding. A letter was read from Mr. Greenwood in which he said he was considering the committee's request for an inquiry into the condition of the deaf. He added that he himself was going into the question. Deputations were received from four nursing organizations, who spoke against the retention on the register of nurses who, though not convicted, had been found guilty of misconduct. The Medical Committee, after careful consideration, decided that it could not usefully act in the matter. Some discussion arose about milk, and the committee learnt that Mr. Greenwood had informed Dr. Fremantle of his intention to have prepared and to publish a report on bovine tuberculosis and its spread from cattle to man. Mr. Greenwood had added that he could not say how long the preparation of this report would require. The Medical Committee further discussed the position under the new Local Government Act of medical men on public bodies. A proposal was made that the Government should be asked to pass an Indemnity Bill protecting those doctors who are now on corporations and also in public posts. The committee showed no unanimity on the matter. It was, however, unanimously in favour of a proposal that the provision of first-aid apparatus should be compulsory on all road vehicles carrying more than six passengers. The honorary secretary of the committee, Mr. Somerville Hastings, was instructed to convey the proposal to the Minister of Transport.

On February 11th Mr. Benson presented a bill to abolish corporal punishment.

The Hairdressers and Barbers' Shops (Sunday Closing) Bill and the Mock Auctions Bill were read a second time without debate in the House of Commons on February 6th.

Psittacosis.

In the House of Lords, on February 5th, Lord OXSLOW asked the Government how many cases of psittacosis, or "parrot disease," had been recorded in the United Kingdom since June 1st, 1929. He further asked what steps had been taken to prevent the spread of the disease, and whether there were any restrictions on the importation of parrots, and, if so, what they were.

Lord DAWSON OF PENN said he wished, before the Government answer was returned, to draw attention to a few facts. This disease had been known for some time, but had only recently become a matter of anxiety in certain districts of England. There was no fear of it becoming rapidly diffused like influenza. It would not spread in a universal way, but would spread in patches. It broke out in families, or small communities of people, and in the patches where it did appear the mortality was liable to be depressing. He gave an instance of this. A boy had bought a parrot a little while ago, and during the incubation period of the disease, which was from ten days to three weeks, the mother noticed that the parrot was not very well. She attended to the bird and cleansed its eyes. Next, the parrot died, and a daughter, who had never had any contact with it during its life, took the body and deposited it in a dustbin. The girl died after a week's illness, and at the time Lord Dawson was speaking the mother and two sons were gravely ill from the disease. Parrots from South America were mainly responsible. Some months ago five hundred parrots were dispatched from the Argentine to France. About two hundred of them died on the way, and the result of the remainder being landed was that France had an outbreak of the disease. The Argentine itself had an outbreak last July. Two courses were open for consideration by the Ministry of Health. One was to put the parrots into quarantine on some remote island, like Lundy Island; the alternative was an embargo. The United Kingdom put an embargo on animals which were likely to be diseased when they were killed, and he suggested to the Government that it would be better to put an embargo on these parrots until the disease had passed. Parrots, after all, were only a luxury, and if they arrived in this country the public would now turn them out into the streets, as had been done frequently of late. Lord Dawson thought that the mere announcement of an intention to impose an embargo would probably stop for the time being the dispatch of parrots to the United Kingdom from the Argentine. He added that he did not think the patches of parrot disease would spread over the country, and he said it was very important that no alarm should arise beyond what was proper and fitting.

Lord MARLEY (Lord-in-Waiting) replied for the Government. He welcomed the intervention of Lord Dawson, who had spoken with authority on the matter. He said that the disease was not compulsorily notifiable, and that, therefore, the Ministry of Health had no complete records of it. Since June 1st, 1929, the Ministry had received information of forty cases in this country, in some of which the available particulars justified only a suspicion of the disease. The Ministry was advised that the danger of the spread of the disease from human cases was practically negligible. If there was no parrot the occupants of a house would appear to be safe. To check the spread of the disease, therefore, the Ministry should rely upon precautions with regard to the parrot itself. The Ministry was advised that the matter might become serious. It had therefore prepared a memorandum setting forth the available information about the disease, and the precautions which should be observed in the care and handling of parrots. This memorandum would be circulated shortly to local authorities, and would be on sale. There were at present no restrictions on the importation of parrots, and he was advised that, under the existing law, they could only be imposed if it were established that they were necessary in order to prevent the spread of the disease. The Ministry felt that further information was necessary before restriction on importation could be justified on grounds of health. Practically no commercial consignments of parrots reached the United Kingdom during the winter months.

Deaths due to Dangerous Drugs.—On February 5th Major CARVER asked the Home Secretary whether he could give any statistics showing the mortality in England and Wales from drugs. Major Carver made this request in view of a statement attributed to one of the British assessors at the recent meeting of the League advisory committee on the traffic in opium and other narcotic drugs. This statement was that the destruction of life caused by the illicit drug traffic could be compared to that of a modern battle. Mr. CLYNES, in reply, said he had seen a press report of remarks made by the president of the Central Opium Board. These remarks obviously related to the world traffic in drugs rather than to the state of affairs in any one country. The Registrar-General had furnished figures relating to deaths from drugs coming within the Dangerous Drugs Act which showed that in England and Wales, in the period 1921–22, there were 18 male and 15 female deaths from opium or other narcotic drugs; in 8 instances death was due to "drug habit" or to the use of narcotics. There were 37 male and 22 female deaths from suicide by opium and other narcotic drugs. Accidental death from opium and other narcotic drugs numbered 95 (male 64, female 31). There was one case of homicide by other means (morphine).

Maternity Benefit Schemes in India.—Mr. BENN told Major Pole, on February 6th, that in June, 1924, in pursuance of a resolution adopted at the Washington Conference, the Government of India undertook an inquiry regarding the extent to which maternity benefit schemes were enforced in India. The result of this inquiry had been published in a bulletin of Indian industries and labour. Since 1925 maternity benefit schemes had been introduced by various Indian employers. Legislation had been passed by the Bombay Legislative Council, taking effect from July, 1929, which provided for the grant of maternity benefit to women employed in factories within that province. A bill on similar lines was under the consideration of the Central Provinces Legislative Council.

Tuberculosis.—Dr. FREMANTLE, on February 6th, asked Mr. Greenwood if, with a view to effective co-ordination of efforts to prevent the spread of bovine tubercle bacilli from cattle to man, and to promote the consumption of milk, he would issue for the guidance of the public a review of the main facts and experience on this question, and set out the conclusions on which action should be based. Mr. GREENWOOD said he had given instructions for the preparation of a report summarizing existing information on this subject.

Tuberculous War Pensioners.—In a reply to Mr. Oliver Baldwin, on February 6th, Mr. F. O. Roberts said it was the practice of the Ministry of Pensions to make final awards in all cases of tuberculosis which were found to be suitable, but, having regard to the nature of the disease, it would not be in the best interests of the pensioners to make such an award as a matter of course.

Vaccination.—Mr. GREENWOOD told Mr. Winterton, on February 6th, that he was not in a position to make a statement on the desirability of a public inquiry into vaccination. Mr. WINTERTON asked whether such an inquiry, if granted, would be based on the model of the Royal Commission on Licensing, and whether the terms of reference would be wide enough to let the whole question be examined. Mr. GREENWOOD said that these questions did not arise.

Maternity and Child Welfare.—On February 3rd Miss LAWRENCE told Mr. West that the Minister of Health had received representations from the Metropolitan Borough Standing Joint Committee with reference to the maternity and child welfare scheme which

he proposed to make under Section 101 (6) of the Local Government Act, 1929. The Minister was satisfied that under the Act he was authorized to confer on the London County Council supervisory powers over certain voluntary associations which were specified in para. 3 of the scheme.

London Maternity Services.—Mr. GREENWOOD informed Sir Kingsley Wood, on February 6th, that he had received the observations of the Woolwich and other metropolitan borough councils on the proposed scheme for maternity and child welfare services under the Local Government Act, 1929, for the County of London. The observations of the borough councils on the scheme were now under consideration. He proposed to ensure the performance by the borough councils of their statutory duties in connexion with this scheme.

Hospitals and Road Traffic Accidents.—Mr. LOUIS SMITH, on February 5th, asked whether the Government was still ready to receive sympathetically representations from the hospitals on the proposal to allocate a certain proportion of money paid under motor car owners' third-party insurance policies to the treatment of injured persons by these hospitals. Mr. HERBERT MORRISON replied that an opportunity for raising this matter would occur on the Road Traffic Bill, and he preferred not to anticipate discussion. Replying to Sir Philip Richardson, on the same day, Mr. Morrison said the Road Traffic Bill contained provisions which would enable him to issue directions for the guidance of all users of the highway, including pedestrians.

Mental Defectives in Scotland.—Mr. JOHNSTON, on February 4th, informed Dr. Forgan that Section 38 of the Mental Deficiency and Lunacy (Scotland) Act, 1913, which authorized Exchequer contributions towards the expenses of societies assisting defectives, was repealed by the Local Government (Scotland) Act, 1929, as from May 16th, 1930. Under the last-mentioned Act contributions for the purposes mentioned might be made by county and town councils, and a scheme providing for such contributions might be made by the General Board of Control. The attention of county and town councils had been drawn to these provisions of the Act.

Flogging as a Punishment in Civil Cases.—Replying, on February 6th, to Mr. Freeman, who asked whether, as flogging, whipping, and birching had been abolished in the navy without discipline having suffered, the Home Secretary would consider abolishing these forms of punishment in civil cases in certain circumstances, Mr. CLYNES said that, though there was a widespread belief in the efficacy of corporal punishment for certain crimes, he thought the position might be reviewed in regard to some offences punishable in this way. He would be glad to take the matter up if a suitable opportunity arose. Mr. SOMERVILLE HASTINGS asked whether Mr. Clynes knew that a man had committed suicide at Wandsworth Gaol to avoid this punishment. He further asked the number of children and adults sentenced to the cat in 1929. Mr. CLYNES said the man in question had killed himself because he feared ten years' penal servitude. The last available figures were for 1928, when thirteen persons over 21 and three persons between 16 and 21 were ordered the cat. Mr. Clynes added that he had no power to forbid a form of punishment prescribed by Act of Parliament. Mr. HASTINGS then pointed out that Mr. Clynes had the right to remit any sentence in the public interest, whereupon Mr. Clynes agreed, and said he considered this in cases which came before him. In reply to a question by Mr. Benson on this subject, Mr. Clynes said he would consider setting up a Select Committee.

Silicosis.—On February 6th Mr. CLYNES informed Mr. Hoffman that he proposed to extend the scope of the Metal-grinding (Silicosis) Scheme to include workers employed on segmental wheels (Slack's machines) fitted with sandstone. He had sent a draft Amending Order to employers' and workers' organizations to give them an opportunity of submitting observations before it was finally made. The Amending Order would take effect on April 1st, and applied to all workmen employed in the processes on or after the date on which the Order was made.

Treatment of Cancer.—Mr. GREENWOOD told Mr. Young, on February 6th, that methods of treating cancer brought to the notice of his department were judged entirely on their merits, irrespective of whether they came from outside the limits of the recognized medical profession or not. Up to the present none had proved, when judged by scientific standards, sufficiently successful to call for action in its support by the Ministry. He had seen nothing of the methods proposed by a certain Mr. Ellis Barker, and was not sure that he was a practitioner. During the period January 1st, 1920, to September 30th, 1929, 42,687 deaths from cancer were registered, of which 23,060 were females. Of the total, 5,155 were persons resident in London. Asked by Major GLYN whether he would consider making cancer a notifiable disease, Mr. GREENWOOD said he would like notice of that question. Cancer was not an ordinary infectious disease. The National Radium Commission could not, he pointed out to Mr. Louis Smith, provide funds for the establishment in the provinces of radium institutions for the treatment of cancer. The Royal Charter by which the Commission was constituted prevented funds from being placed at its disposal for the purpose indicated in the question.

Hospital Treatment for Orthopaedic Patients.—Mr. GREENWOOD, on February 6th, informed Colonel Acland-Troyte that local sanitary authorities already had power to provide all necessary hospital treatment for orthopaedic patients. Under Section 11 of the Local Government Act, 1929, county councils would have this power from April, whether for children or adults.

Position of Medical Members of Local Authorities under the New Local Government Act.—On February 6th Major MCKENZIE Wood asked the Minister of Health whether he proposed to introduce legislation to relieve medical practitioners of disabilities arising out of contracts with local authorities of which they were members, and, if so, whether he would consider the position of other members of county councils who might have received contracts placed by bodies of which they are not themselves members, but whose duties are about to be taken over by committees of the new county councils. Mr. GREENWOOD replied that the recommendations of the Royal Commission in regard to medical practitioners were under his consideration. He did not contemplate legislation to remove disabilities of persons who were now members of local authorities and might become disqualified by operation of law on April 1st. The latter part of the question, therefore, did not arise, though he agreed that the principle would apply to a much wider circle of people.

Treatment of Mental Patients.—In reply to Mr. Freeman, on February 6th, Mr. GREENWOOD said the maintenance of lunatics in cottage homes as an alternative to large institutions was under consideration, though he was advised that the majority of patients could not be suitably provided for except in institutions. Mr. SCRYMGEOUR asked whether he knew of the poor results of placing patients in large institutions in contrast with private establishments. Mr. GREENWOOD replied that he feared Mr. Scrymgeour's facts were wrong, but he was prepared to discuss the question. In reply to Captain Gunston, he said that the Mental Treatment Bill would be dealt with as soon as possible. Mr. FREEMAN asked why mental patients were kept in large institutions at present. Mr. GREENWOOD replied that there were cases which required the constant assistance of people who understood mental diseases.

Chemical Warfare.—Mr. SHAW, on February 4th, told Mr. Ayles that research work on protection against chemical warfare was still carried out at the laboratories at Porton and Sutton Oak.

Medical Care of Soldiers' Families.—Answering Major Glyn, on February 4th, Mr. SHAW said that the families of soldiers on the married quarters roll were eligible for medical treatment at the public expense at all stations, but only provided that military medical facilities existed. At certain large stations, including the Cambridge Hospital, Aldershot, the Royal Herbert Hospital, Woolwich, and the Netley Hospital, Portsmouth, there was a military specialist in diseases of the ear, nose, and throat. Families of soldiers on the married quarters roll had the benefit of his services. In accordance with general policy, no payment was made from army funds for special civilian medical attendance for these diseases where no military specialist was available.

Foot-and-Mouth Disease.—On February 10th Mr. BUXTON, replying to Lieut.-Colonel Windsor-Clive, said that in the last five years there had been 783 outbreaks of foot-and-mouth disease in Great Britain, and 64,916 animals had been slaughtered. The total number of animals found affected with the disease during that period was 10,235.

Training of Veterinary Surgeons.—Dr. FREMANTLE, on February 10th, asked the Minister of Agriculture if it was not very important for the Minister to deal with the training of veterinary surgeons. Mr. BUXTON replied that the urgency of this matter was great. Arrangements were being made to deal with the reconstruction of the Royal Veterinary College by the department concerned.

Disposal of House Refuse.—Miss LAWRENCE, replying to Sir P. Cunliffe-Lister, on February 10th, said that she was aware that the Harrow Urban District Council proposed to use the space known as the Brickfield, West Harrow, for a dumping ground for house refuse. The Minister had received representations from householders in the neighbourhood protesting against the proposal, as being a serious menace to the health of themselves and their children. A public inquiry would be held into the proposal on February 12th by an inspector of his department. Dr. FREMANTLE asked whether the Minister of Health would accelerate the publication of the report of the Departmental Committee which he appointed to deal with the whole subject of the disposal of refuse. Miss LAWRENCE said that the Departmental Committee, after much delay, owing to the death of its chairman, was nearly at the end of its labours. She had every hope that it would report shortly.

Small-pox.—On February 10th Mr. GREENWOOD, replying to Mr. Groves, said that in 1929 six deaths were certified as due to small-pox among persons whose usual place of residence was in the administrative County of London. This figure was provisional. On February 11th Mr. Greenwood told Mr. Freeman that he was advised that there were many considerations affecting the duration of the protection against small-pox which was afforded by vaccination. He referred Mr. Freeman to para. 377 of the final report of the Royal Commission on Vaccination made in 1896, in which these considerations were reviewed and summarized. He had no information as to how many of the adult population were revaccinated.

Leave of Officers in the Colonial Medical Service.—On February 11th Dr. DRUMMOND SHIELS, replying to Dr. Morgan, said that the conditions governing the grant of leave to officers of the Colonial Medical Service were the same as those governing the grant of leave to other colonial Government officials, and were set out in the Colonial Regulations, which were reproduced in the Dominions Office and Colonial Office List. The conditions varied considerably in the different colonies, the main ground of variation being differences of climate. The grant of leave was in all cases at the discretion of the governor of the colony concerned, and dependent on the exigencies of the service, but an officer would only be refused leave for which he was eligible under the regulations on grounds of the right of the public interest. Medical officers, like other officers, had the right of appeal to the Secretary of State if they were dissatisfied with the decision of the governor. Special regulations were in force with regard to study leave for medical officers in various colonies.

Medical News.

THE 157th anniversary dinner of the Medical Society of London will be held at the Hotel Cecil on Thursday, March 6th, at 7.30 for 8 o'clock.

THE Countess of Birkenhead and Lady Northcote will hold a reception at the General Lying-in Hospital, York Road, Lambeth, on February 18th, at 3.30 p.m., to welcome Dame Janet Campbell, senior medical officer for maternity and child welfare, Ministry of Health, on her return from the Commonwealth of Australia.

A JOINT meeting of the Sections of Obstetrics and Electrotherapeutics of the Royal Society of Medicine will be held at 1, Wimpole Street, W.1, on Friday, February 21st, at 8 p.m., when there will be a general discussion on the position of radium in the treatment of gynaecological conditions. The debate will be opened by Mr. Malcolm Donaldson and Mr. Stanley Dodd on behalf of obstetrics, and by Mr. A. E. Hayward Pinch and Dr. J. E. A. Lynham from the electrotherapeutical standpoint.

THE monthly meeting of the British Institute of Radiology will be held at 32, Welbeck Street, W., on February 20th, at 8.30 p.m., when Dr. A. E. Barclay will read a paper on the mechanism of swallowing. Mr. J. Preston Maxwell one on osteomalacia and foetal rickets, and Dr. John Muir one entitled "The irritable colon."

A MEETING of the West Kent Medico-Chirurgical Society will be held at the Miller Hospital, Greenwich, S.E.10, to-day (Friday, February 14th), at 8.45 p.m. Dr. Harold Pritchard will read a paper on some points in diagnosis and treatment of peptic ulcer.

THE annual meeting of the Industrial Health Education Society will be held at the House of the British Medical Association, Tavistock Square, W.C.1, on February 18th, at 4 p.m., with Sir William S. Haldane in the chair. The annual report will be presented by the honorary secretary, Dr. G. Clark Trotter.

THE first Pan-Hellenic Health Conference will be held at Athens next April, and in connexion with it the Greek Medical Association is arranging an exhibition relating to hygiene in general, to which it is hoped that a large number of exhibits from other countries will be sent. It is announced that such exhibits will be exempt from customs duties, and should be sent before March 31st to the offices of the organizing committee of the conference, Odos Kriezotou 1, Athens.

A NEW series of conducted tours under the auspices of King Edward's Hospital Fund for London has been arranged to take place in February and March. On February 26th the Houses of Parliament will be visited, and on later dates the Foreign Office, India Office, and Home Office Industrial Museum. Particulars and tickets (price 10s. for each occasion) can be had from the secretary of the Fund, 7, Walbrook, E.C.4.

DR. THOMAS TENNENT will lecture for the Fellowship of Medicine on the malaria treatment of general paralysis at the lecture hall of the Medical Society, 11, Chandos Street, Cavendish Square, on Tuesday, February 18th, at 4 p.m. On February 19th, at 3 p.m., Dr. C. M. Wilson will demonstrate special cases and out-patients at St. Mary's Hospital, Paddington; and on the same date, at 2 p.m., Mr. Gill-Carey will demonstrate by operation on selected ear, nose, and throat patients at the Central London Throat, Nose and Ear Hospital, Gray's Inn Road. *There is no fee for attendance* at the lecture and these demonstrations. From February 17th to March 15th there will be an afternoon course at St. John's Hospital, Leicester Square, consisting of instruction in the out-patient department and bi-weekly lectures; practical pathology classes can be arranged. From February 24th to March 8th a course in diseases of children will be held at the Children's Clinic in association with other hospitals, occupying some mornings and some afternoons, and including visits to interesting centres of infant welfare work. An afternoon course consisting of demonstrations on the diagnosis and treatment of the eye will be conducted at the Royal Eye Hospital from February 24th to March 8th. The courses in March relate to: diseases of the chest and nerves; orthopaedics; venereal diseases; medicine, surgery, and gynaecology, and gastro-enterology. Some of these courses continue into April. Copies of all syllabuses and of the *Post-Graduate Medical Journal*, together with information regarding the general course of work at the associated hospitals, may be obtained from the secretary of the Fellowship, 1, Wimpole Street, W.1.

THE spring session of training courses arranged by the Royal Sanitary Institute for examinations for meat and food inspectors, and the associateship of the institute in food hygiene, will commence on Friday, February 21st. Syllabuses of the lectures and examinations are obtainable from the secretary of the Institute, 90, Buckingham Palace Road, S.W.1.

A MEMORIAL to the late Sir William Glyn-Jones was unveiled at the House of the Pharmaceutical Society of Great Britain, Bloomsbury Square, W.C., by Dr. Christopher Addison, M.P., Parliamentary Under-Secretary to the Minister of Agriculture, on February 5th. The memorial takes the form of a bronze bust surmounted by the arms of the society in enamel.

THE Committee for the Study of Medical Hydrology in Great Britain has at its disposal the services of a number of physicians in London and the spas of Great Britain who are *specially qualified to lecture on medical hydrology and spa* treatment. In addition to giving lectures to senior medical students, post-graduate associations, and medical societies, the committee will be glad to arrange for visits of such associations to any of the British spas for lecture-demonstrations. Further particulars may be obtained from the honorary secretary, Dr. Geoffrey Holmes, 11, Ripon Road, Harrogate.

AS will be seen from our advertisement pages, the Council of the Royal Society of Medicine has accepted as a trust the sum of £1,000 presented by Mr. Norman Gamble for the purpose of providing a prize of £50 every fourth year for the best original work in otology carried out by a British subject during the preceding four years. The balance of the fund is to be used for the purpose of awarding grants in aid of research work in otology. Copies of the regulations governing the award can be obtained on application to the secretary of the Royal Society of Medicine, 1, Wimpole Street, W.1, to whom applications for the prize and for grants in aid must be sent not later than September 30th.

THE following course of post-graduate lectures will be given at the Royal Dental Hospital of London, Leicester Square, W.C.: March 5th, Mr. Bowdler Henry—Inter-relationship of mouth and bowel; March 12th, Dr. I. H. Maclean—Rosenow's theory of elective localization; March 19th, Dr. E. W. Fish—A theoretical review of treatment of the dentine: March 26th, Mr. J. G. Turner—Extraction; April 2nd, Dr. F. P. de Caux—Recent advances in the methods of administering N_2O in the surgery of the mouth; April 9th, Dr. F. Talbot—Trigeminal neuralgia as it occurs in the electro-therapeutic department. The lectures will be delivered at 6 p.m. each day; they are open to practitioners and advanced students.

A SECOND tour for medical men to the climatic and hydromineral stations of Spain has been arranged for Easter. The party will leave Barcelona by special motor boat on April 13th, visiting Palma (Majorca), Alicante, Malaga, Seville (in time for the Good Friday procession), and Valencia, returning to Barcelona on April 23rd. There will be an opportunity of seeing the exhibitions at Barcelona and Seville. The price from Barcelona is from 1,000 to 1,600 French francs, according to the cabin occupied. Further information may be had from Dr. Mañeru, Ronda del Conde Duque No. 4, Madrid.

A SERVICE *in memory of the late Dr. Daniel L. Thomas*, medical officer of health for the borough of Stepney for twenty-nine years, was held on February 9th at St. Dunstan's parish church, Stepney. It was attended by the mayor and other municipal representatives.

THE People's League of Health tenth travelling scholarship will be competed for in connexion with the annual series of Sims Woodhead Health Educational Lectures. These lectures will be delivered by leading medical men and scientists at the headquarters of the National Union of Teachers, Hamilton House, Mabledon Place, W.C.1, commencing on March 3rd, for twelve consecutive Mondays, with the exception of Easter Monday (April 21st). At the end of the course, those who have attended nine or more lectures will be entitled to enter for the examination.

IN connexion with the first International Congress of Mental Hygiene in Washington, which will be held in May, a tour of North America has been arranged by the Hamburg-American Line, commencing on April 23rd, when members will meet in Hamburg. Two days later they embark on the ss. *New York*, which on the following day will call at Southampton and Cherbourg. The passenger agents in London for the Hamburg-American Line are Wm. H. Müller and Co., Ltd., 66–68, Haymarket, S.W.1.

DR. MARY THORNE has been appointed a justice of the peace for the county of London.

PROFESSOR LÉON BERNARD has been elected president of the French Council of Public Health.

DR. JULIUS DONATH, professor of nervous diseases at Budapest, has recently celebrated his eightieth birthday, and Professor Otto Lubarsch, who formerly held the chair of pathology in Berlin, his seventieth birthday.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863, and 9864* (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediocera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

SCARRING AFTER EPILATION.

"JUVENTAS" asks for advice in the treatment of a lady who had superfluous hairs removed—on the Continent—with diathermy, and who now has scarring where this has been done.

DANISH TREATMENT OF ITCH.

DR. T. DOUGLAS ROSS (Glasgow) writes: Following Dr. Cannon's direction in his recent article on the Danish treatment of itch (*Journal*, January 25th, p. 148), I find it impossible to dissolve 1 kg. of sublimated sulphur in 1 kg. 50 per cent. KOH completely, so as to give a clear yellow solution. Gentle heat merely blackens the mixture. I should be obliged if he would point a way out of this difficulty.

PRURITUS.

DR. W. H. DAVIES writes: I shall be grateful for any help your readers can give me for treating a case of "generalized pruritus," associated with impotence, in a man aged 43. He has had all the usual local and internal remedies, including gland therapy.

PRECIPITATE EJACULATION.

"N. D." writes: I should be grateful for suggestions as to treatment of a case of premature ejaculation in an otherwise healthy man of 45. He states that though erection and emission occur normally, the whole process is over in a few seconds, and he is therefore unable to satisfy his wife. In all other respects their marriage is a normal, fertile, and happy one, but the condition described is beginning to tell on their nerves. Various organic extracts of testicle, etc., have been tried and found useless. It is possible that Steinach's vaso-ligation might help, but before recommending this I should like the experience of others who have had to deal with such cases.

GLASS PERMEABLE TO ULTRA-VIOLET RAYS.

"FORTY YEARS A SUBSCRIBER" writes: I have been much interested in the articles which have appeared in the *British Medical Journal* about glass permeable to ultra-violet rays, but before adopting it in my new dwelling-house I would be glad to have independent and authentic information on several points which occur to me. What exactly are the virtues claimed for it? Does it really possess these virtues, and does it retain them unimpaired indefinitely, or does it lose them as time goes on? Is it injurious to the eyes or in any other way? Does its use result in fading of curtains, carpets, etc? Would it be desirable to put it in *all* windows of a dwelling-house?

*** We have submitted this query to a correspondent with special experience, who writes as follows:

The sun's radiance gives a very wide spectrum, of which only a very small part is visible; immediately beyond the violet end are radiations having a high actinic power, and commonly known as ultra-violet rays. These are filtered off to a large extent by the atmosphere; they are plentiful in the High Alps, but scarce in the smoky, misty air of many northern towns. Ordinary window glass also excludes them. The benefit to the body metabolism of a reasonable exposure to ultra-violet radiations, whether from a natural or an artificial source, is now known. Vita glass is one of a number of transparent substances that have been devised with a view to getting a form of window glazing that will admit these beneficial rays. There is no doubt that these glasses do achieve this aim; it is true that, after a time, the glasses lose some of their initial virtues, but they retain permanently a high degree of permeability to ultra-violet radiation. Their use does not result in injury to the eyes, any more than does the sunshine out of doors, though some people prefer their spectacle lenses to be impenetrable to ultra-violet rays. In excess, as on the snows of the High Alps, ultra-violet rays are injurious and cause snow blindness. The special glass is more costly—by some 25 per cent.—than ordinary window glass. Its advantage in town will depend on the clearness of the air and its freedom from smoke, and also on *the frequency with which the windows are cleaned*; a film of smoke on the glass speedily reduces its value. There is nothing gained by putting the glass into windows that have no clear skyscape. For those who spend much of their time out-of-doors there is small need for special provision; for invalids who cannot get out of doors the use of a special glass is an advantage. Paintings, curtains, and carpets are likely to be adversely affected, more than they are by exposure to light passing through ordinary glass, but fabric dyes are now greatly improved and are nearly fast.

INCOME TAX.

Temporary Cessation of Foreign Employment.

"E. C." is employed abroad by—we assume—a foreign or colonial concern, and proposes to come to England "for about a year" as from September next. He will receive a gratuity on arrival, and will arrange for the remittance to England from abroad of a sum of £1,000 to cover his expenses. Will he be liable to income tax in this country?

*** We assume that he has not been maintaining a residence in the United Kingdom during his absence. If he intends to return to colonial work it is clear that he will be coming to the United Kingdom "for a temporary purpose only," and therefore will not become a "resident" for income tax purposes unless he spends six months in any particular financial year in this country. Consequently he will not become a resident for the year ending April 5th, 1931 (unless he lands on or before October 5th, 1930), and therefore will not be liable in respect of the payment of £200. The £1,000 represents capital in this country, and would not be taxable, but if he is in the United Kingdom for six months of the year commencing April 6th, 1931, he will become an "occasional resident," and will be liable in respect of any income from investments that may be remitted to him here.

Keep of Assistant.

"L. H. E." inquires what figure is usually taken as a reasonable amount to charge in respect of the keep of an assistant who lives in.

*** Circumstances vary so much, according to locality, domestic conditions, etc., that it is almost impossible to suggest a "usual" figure, but the amount of £1 per week which the inspector of taxes suggests seems abnormally low. We should regard £2 per week as normal, to include bedroom and service, but that suggestion should be taken as only tentative. It is, after all, a question of fact—that is, by how much the food costs have been increased by the assistant, and what is a fair allocation of the general expenses, rent, rates, domestic service, etc.

LETTERS, NOTES, ETC.

LARGE HYDROCELES.

"E. M. L." (London, S.W.) writes: Dr. P. M. Shepherd's patient's double hydrocele of an aggregate of 101 oz. (February 8th, p. 263) was a respectable swelling, but I believe that the record for a single hydrocele is still held by the six quarts of Edward Gibbon the historian, which must have been very disfiguring in those days of tight breeches. Gibbon himself seems to have had doubts as to this, for he wrote to Lord Sheffield: "Have you never observed, through my *incrpressibles*, a large prominency, which, as it was not at all painful and very little troublesome, I had strangely neglected for many years?" Even if the six quarts were of only 32 oz. each, instead of the 40 oz. of imperial measure, the total of 192 oz. overtops the Nigerian's 61.

THE ACCOUCHEUR'S NAIL BRUSH.

DR. R. MACKINNON (Oldham) writes: In view of the correspondence about maternal mortality from sepsis, I wonder how many cases could be traced to the nail brush which is part of the equipment of every midwifery bag. It is impossible to get it efficiently sterilized, and is at any time a danger to patient and operator alike.

A WARNING.

DR. A. NELL, who was in this country for some months last year and attended the Manchester meeting as representative of the Ceylon Branch, writes: After my return to Kandy I have learnt that some-one calls on, or writes to, people in England pretending to be me. This is to warn my fellow practitioners.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 47, 48, 49, 50, 51, 54, 55, and 56 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 52 and 55.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 55.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

156. Chronic Idiopathic Secondary Anaemias.

C. H. WATKINS (*Journ. Amer. Med. Assoc.*, November 2nd, 1929, p. 1365) classifies chronic idiopathic anaemias into four morphological types. The first type occurs in young women or girls, and shows a moderately reduced haemoglobin percentage, a slightly reduced red cell count, and a lowered colour index of 0.5 to 0.6; the red cells have marked "anachromasia," a piling up of the haemoglobin in a narrow peripheral ring, leaving a colourless central area; the leucocytes are normal. This is known as the chlorotic type, and is treated with iron and improved hygienic conditions. In the second type there is a proportional reduction of the haemoglobin and red cells, so that the colour index remains about 1; the red cells show only slight anachromasia and anisocytosis; there is slight leucopenia with relative lymphocytosis, and the neutrophils are decreased in size but show increased lobulation of the nucleus; the blood picture is described as "aged," suggesting some dysfunction of the bone marrow. This is known as the semi-aplastic type, and is treated by transfusion of whole blood, extract of bone marrow, and a diet rich in iron. The third type appears as an insidious anaemia occurring in women aged 50 to 60, which may be associated with achlorhydria; the red cell count is normal or increased, but the cells are markedly hypochromasic or pale, the haemoglobin being reduced to 45 per cent.; reticulocytes are increased, and the leucocytes are normal in count and in appearance. Here the dysfunction is the synthesis of haemoglobin; treatment with a powder made from foetal calf liver, in doses corresponding to 300 grams of raw calf liver daily, has given good results. The fourth type occurs in young persons with a family history of pernicious anaemia; there is slight lowering of the haemoglobin percentage and the red cell count, with a colour index under 1; the increased lobulation of the nuclei of the neutrophil leucocytes resembles that met with in pernicious anaemia. These cases react quickly to raw liver or liver extracts.

157. Haemochromatosis.

F. C. WOOD and T. FITZ-HUGH, jun. (*Arch. Int. Med.*, December, 1929, p. 882) report a case of haemochromatosis in a metal worker. Clinical and laboratory studies were undertaken in order to ascertain the relationship, if any, between copper poisoning and haemochromatosis, the value of insulin in controlling carbohydrate disturbances in a progressive pancreatic disease complicated by hepatic disorder, and the effect upon other endocrine glands. A man, aged 48, had suffered for two years from attacks of epigastric pain three hours after meals; they were relieved by food and the administration of sodium bicarbonate, but for a year he had noticed a progressive dark coloration of his hands, forearms, and face. Two months before admission to hospital he began to lose weight, and diabetes mellitus developed, with blurring of vision, dyspnoea and palpitation on exertion, loss of libido, and numbness and tingling of the finger-tips. He had worked for twenty years mainly with steel and brass and rarely with copper, the dust from grinding impregnating his clothes. There was no history of venereal disease or intemperance. The diagnosis of haemochromatosis was based upon the classical picture of a man in middle life with hepatic cirrhosis, diabetes, and pigmentation. The course of the disease tended steadily downwards, a high blood sugar figure persisting in spite of large doses of insulin; there was recurrent ascites with progressive emaciation and diarrhoea. The urine contained sugar throughout; the urobilin reaction was strongly positive and there was a trace of bilirubin at times. A biopsy of the skin and a lymph gland showed haemosiderin in considerable amounts, but no copper was demonstrable. The patient died in coma from peritonitis. The post-mortem examination showed hepatic cirrhosis and marked haemosiderin pigmentation of the liver and pancreas; a considerable amount of haemosiderin deposit was found in the heart muscle, and especially in the retroperitoneal lymph glands in the neighbourhood of the liver and pancreas. The icterus index tests failed, owing to discoloration of the serum from haemolysis; this, the authors suggest, may point to some underlying factor not yet understood, and deserving further investigation. From this case and a review of the literature they conclude that chronic copper poisoning has not yet been proved to be a causative factor in this morbid condition.

158. Typhoid Fever due to a Surface Well.

E. G. MORALES (*Amer. Journ. Pub. Health*, September, 1929, p. 937) describes an epidemic of 42 cases of typhoid fever following a hurricane in September, 1928, in a semi-rural village in Porto Rico. The suddenness of the outbreak, together with the high incidence rate among the population in the village, immediately suggested a vehicle in use by a large proportion of the inhabitants as the chief causal factor. Water from the public supply was eliminated. The suspicion that water from a surface well used by about one-half the persons in the village was responsible was confirmed by epidemiological investigation. Although the persons who used water from the well formed only 51 per cent. of the population of the village, this group contributed 92 per cent. of the cases, and infection in two out of only three cases who did not use this water supply was attributable to contact with previous cases.

159. Eruptions in Meningococcal Septicaemia.

R. PITOU (*Thèse de Paris*, 1929, p. 6243), who records four illustrative cases, three of which were in soldiers and one in a soldier's son aged 4, states that meningococcal septicaemias are frequently accompanied by eruptions which may affect the skin and mucous membranes. The skin eruptions may be of three kinds: (1) erythema, which may be papulonodular, morbilliform, scarlatiniform, or lenticular rose spots; (2) vesicular, which may be herpetiform, varicelloid, or purpuric with secondary vesicle formation; and (3) due to vascular lesions giving rise to purpura. These meningococcal eruptions, which are due to the vascular and perivascular localization of the meningococcus, may accompany or precede cerebro-spinal meningitis. Pitou remarks that eruptions unaccompanied by cerebro-spinal meningitis are very important, since early treatment by the intraspinal and intramuscular injection of antimeningococcal serum may prevent its occurrence.

160. Prophylaxis of Measles in Scarlet Fever and Diphtheria Patients.

A. LICHTENSTEIN (*Acta Paediatrica*, September 30th, 1929, p. 77) has found that the ordinary doses of convalescent measles serum (2–3 c.cm.) which were successful in the case of healthy children completely failed to protect children who were suffering from scarlet fever or diphtheria. In the case of scarlet fever five to ten times the ordinary dose (15–30 c.cm.) was required, while in the case of diphtheria the dose had to be three to six times higher than usual.

Surgery.

161. Thrombosis of Superior Mesenteric Vein.

J. WULSTEN (*Zentralbl. f. Chir.*, December 14th, 1929, p. 3155), who records an illustrative case, states that a study of the literature since 1860 shows that, owing to the severity of the disease, recovery from mesenteric thrombosis after operation is very rare, only one example, published by Doerfler in 1923, having hitherto been recorded of recovery after total resection of the small intestine. Reich in 1913 collected 250 cases of mesenteric thrombosis which had been published since 1890. Of 214 cases, 100 (47 per cent.) were caused by arterial occlusion, and 114 (53 per cent.) by venous occlusion. Arterio-sclerosis was almost always the primary disease. Autochthonous occlusion was rarer than embolic. The causes alleged were cirrhosis of the liver, alcoholism, and obesity. Thrombophlebitis of the lower extremities was frequently present. The intestinal lesion was usually a haemorrhagic, and less frequently an anaemic, infarct. In venous occlusion more sero-haemorrhagic exudation is found in the abdomen than in the case of arterial occlusion. Most of the infarcts (199 cases) have been found in the superior mesenteric vessels, as compared with only 9 in the inferior. In 10 cases both superior and inferior mesenteric vessels were occluded. All the cases of venous thrombosis were aseptic. Of 91 patients operated on in Reich's series 75 died, including 43 in whom peritonitis was already present or developed subsequently. During the last sixteen years cases of mesenteric thrombosis have been recorded by W. Wolff (1919), Brütt (4 cases in 1922), Doerfler (1923), Bruns (1924), Klein (24 cases in 1926), and Petermann (1926). Wulsten's patient was a man aged 64, the subject of alcoholism and varicose veins, in whom the diagnosis of

mesenteric thrombosis was made before operation; eleven feet of the small intestine which showed typical haemorrhagic infarction were resected. The superior mesenteric vein and its finest branches were found to be completely thrombosed. Recovery ensued.

162. Fractures of the Pelvis.

S. W. BOORSTEIN (*Amer. Journ. of Surg.*, November, 1929, p. 633) points out that with the increase in the number of automobile and industrial accidents there is also an increase in cases of fractures of the pelvis. The fracture is almost always caused by great violence, falls from heights, or crushing between two moving objects, the motor car being the most frequent offender. Injuries of the pelvic ring comprise the following types: fracture of the rami of the pubis, multiple fractures of the pelvic ring, separation of the symphysis pubis, and dislocation of the sacro-iliac joint. The commonest type of fracture is that of the rami of the pubis. The diagnosis is comparatively easy if the irregular bones of the pelvis and ileum are examined both inside and outside. The two ilia should be pressed together to detect crepitus, rectal and vaginal examinations should also be included, and *x*-ray investigation will indicate the exact position of the fracture. The chief complications are rupture of the bladder, urethra, or bowel, and occasionally rupture of the kidney. The prognosis is good, union occurring in from eight to ten weeks. The patient can be up in six weeks, and complete recovery is attained in about three months, though men who have to do heavy work should not resume their occupation for six months. Treatment consists in placing the patient on a Bradford frame, which with strapping of the pelvis is all that is necessary in the majority of cases; manipulative reduction is considered unsafe and should not be attempted.

163. R. COLP and R. T. FINDLAY (*Surg., Gynecol. and Obstet.*, December, 1929, p. 847) state that, in this industrial and mechanical age, fractures are not unusual occurrences, and the incidence of certain fractures—for example, those of the pelvis—has increased materially. A series of 35 cases of pelvic fractures is reviewed, the group including not only fractures of the os innominatum, but also traumatic separations of the symphysis pubis and the sacro-iliac synchondroses. As would be expected, more than half of the patients were between the third and fourth decades, the period of greatest physical vigour. The nature of the trauma producing the injury may be one of three varieties: injury by falling, crushing, or collision. The diagnosis of fracture of the pelvis rarely presents difficulty. A fracture of the pelvis was, in the authors' series, invariably accompanied by other fractures, and, in addition to these, by other injuries; most of these complications were caused by the initial trauma. The chief symptom is pain, which is referred to various regions; other symptoms are tenderness, swelling, subcutaneous haemorrhage, haematuria when the bladder is injured, and shock. In many instances certain abdominal symptoms were present, due probably to reflex spasm incident to pelvic fractures. Crepitus is an unusual physical sign in this type of fracture. The treatment of these cases resolves itself into treatment of the fracture and complications. Rest in bed is most important, and in the majority of the cases was the only treatment given. Patients were kept in bed for an average of thirty days, and were allowed up only gradually, the length of time after injury that they were allowed to walk averaging thirty-eight days. Six patients, all with definitely complicated conditions, died, and the fractures of the pelves played only a small part in the causation of death. In the remaining cases the most prominent late symptom was pain. Physical examination revealed only slight deformity and bulging of the pelvis on one side, slight tenderness at the site of the fracture, and in only one case, a fracture of the acetabulum, was shortening present. The authors emphasize the simplicity of the treatment; operations were performed only when complicating injuries to soft parts required them.

164. Surgical Significance of Non-suppurative Encephalitis.

F. BREUER (*Deut. Zeit. f. Chir.*, December, 1929, p. 303), who records numerous examples, maintains that in a number of cases described as encephalitis surgical treatment may be of benefit, and that in many post-traumatic changes in the brain, where the inflammatory character is not very obvious, inflammation really does play an important part in the etiology of the condition. Epileptiform attacks following encephalitis have long proved to be suitable cases for surgical treatment, especially in the case of the residues of encephalitis in children. In one of such cases in which surgical treatment has consisted in excision or drainage the condition has been one of scar formation in the arachnoid or in the actual brain substance, or of cyst formation.

Therapeutics.

165. Cardio-vascular Treatment in Pneumonia.

J. BRODIE (*Canadian Med. Assoc. Journ.*, November, 1929 p. 541) states that it is generally agreed that failure of some part of the circulatory system is an important factor, often leading to a fatal outcome, in many cases of pneumonia. The mechanism of the failure of the circulation is not well understood, since pneumonia produces no definite anatomical changes in the heart, as do some other infectious fevers. But there are certain factors in this disease that must throw an extra burden on the heart; among these are impairment of the pulmonary circulation, disturbance of respiratory function which causes anoxaemia, and toxaemia. The strain on the right heart resulting from impairment of the pulmonary circulation, the widespread pernicious effects of anoxaemia on the whole cardio-vascular system, and the weakening of the peripheral circulation caused by the toxaemia, not to mention other factors, all affect the circulatory apparatus in so many vital points that it often becomes exhausted, and finally breaks down. In treating pneumonia complete physical and mental rest is of supreme importance, and to obtain this the administration of an opiate or morphine is often wise when signs of excessive secretion in the air passages are absent. Opiates should be replaced by milder sedatives after the fourth day of the disease. Digitalis may be given as a routine measure in all cases of pneumonia. In order to avoid over-digitalization, 40 to 60 minims of the tincture, or a corresponding dose of the powdered leaf, should be given daily until the fifth day, when the amount is reduced to 30 minims daily, watch being kept for the usual toxic effects of the drug. The effective administration of oxygen in adequate dosage is supportive, and tends to prolong life until the mechanism of immunity is able to accomplish recovery. Six of the so-called cardiac stimulants are discussed. Alcohol is only a sedative, and may be of value as such; the administration of large, repeated doses may do harm by hampering the production of immunity. Strychnine is unsatisfactory, both as a cardiac and as a respiratory stimulant. Adrenaline is useful when the blood pressure falls and the heart sounds grow feeble; its use needs caution, and small repeated doses are safer than a single large one. Pituitrin is also useful, but less so than adrenaline. The efficacy of caffeine is doubtful. There is no proof that camphor acts on the heart muscle, although it appears to exert some reflex influence on the medullary centres.

166. Treatment of Chronic Rheumatism.

A. GOVAERTS (*Bruxelles-Méd.*, November 24th, 1929, p. 89) claims to have had good results in chronic rheumatism from the intramuscular injection of iodine (3 per cent.) and salol (20 per cent.) in olive oil; 5 c.cm. of this mixture is injected into the gluteal region every second day. The number of injections necessary varies with the case; as a rule no change occurs until six or seven injections have been given. The author's cases were mostly muscular rheumatism or sciatica. Of 229 cases so treated complete and permanent amelioration followed in 60 per cent.; slight but persistent improvement in 10 per cent.; temporary benefit in 25 per cent.; and no good result in 5 per cent.

167. The Salt-free Diet in Tuberculosis.

G. APITZ (*Deut. med. Woch.*, November 15th, 1929, p. 1918) remarks that although a salt-free diet has been tried in several sanatoriums the results have been disappointing. Careful study of the reports of 53 children with surgical and pulmonary forms of tuberculosis who were so treated revealed that a salt-free diet had a definite influence on tuberculosis of the skin, but in all other cases the results were no better than those obtained from ordinary sanatorium treatment. Among 48 children suffering from pulmonary tuberculosis and treated by a salt-free diet, 29 were open cases, and of these 19 died, 4 are still under treatment, while the remaining 6 children were discharged "improved." The other 19 early cases of pulmonary tuberculosis were apparently non-infective and were discharged as definitely improved, but Apitz adds that since these latter patients were early cases, under ordinary sanatorium treatment, the improvement cannot be attributed to the salt-free diet. In all cases there was at first a rapid increase in weight. The course of the disease and the physical signs (confirmed by skiagrams) fluctuated as in other children who were taking ordinary diet. The combined experience of several sanatoriums shows that the final results were no better among patients on a salt-free diet than among those on an ordinary diet. Apitz observes that Sauerbruch's original article advocating this diet was based on a single case of tuberculosis, and he concludes that not only is it valueless as a method of treatment, but that it has been actually harmful when employed to the exclusion of older, well-tried methods.

Disease in Childhood.

168. Reduction of Infantile Mortality in Crèches.

D. LONGPRÉ (*Canadian Med. Assoc. Journ.*, October, 1929, p. 405) deplores the use of the loose term "crèche disease," commonly denoting a series of maladies frequent in crèches but also found in ordinary homes, the infections being particularly fatal. He asserts that the unfavourable statistics of such institutions in comparison with those of children's hospitals are attributable mainly to the unavoidable spread of infectious diseases in a large community, and to the large proportion of cases of prematurity. Of the most important diseases contributing to the crèche mortality, Longpré states that the definitely infective forms of diarrhoea are completely preventable by proper precautions; cholera infantum has been virtually banished, while diarrhoea due to over- or under-nutrition has become much more tractable since the advent of a better understanding of the principles of artificial feeding. Stress is laid on the frequency with which diarrhoea is symptomatic of septic infection, and particularly of unsuspected middle-ear infections. Diphtheria now causes fewer deaths than formerly, active immunization by toxin-antitoxin mixture, and subsequently antitoxin alone, having done much to reduce its incidence, not only in its usual form, but also in its masked form of diphtherial middle-ear infection and chronic rhino-pharyngitis. Measles and whooping-cough are still frequently fatal, through the pneumonias secondarily produced; the special danger attendant on the difficulty of recognizing the latter in its earliest stages emphasizes the necessity of isolating every suspicious case completely from the start. Scarlet fever has been much less frequently found since the commencement of immunization with streptococcal antitoxin. Chicken-pox, elsewhere often a trivial complaint, often proves fatal in crèches where many debilitated children are brought together, on account of the development of pyodermia; sufficiently rigorous isolation of the attendants as well as the patients in this, as in the other infectious diseases, is the only solution of the mortality problem. The common cold has its train of respiratory complications, and until a sufficiently large staff renders it possible to exclude from attendance on the children every person suffering from this complaint this cause of mortality will remain active. Another disease especially common in crèches is gonococcal vulvitis; this is always endemic, and a special danger to debilitated infants. The treatment of rickets and tetany has improved greatly in recent years, ultra-violet light being a useful adjunct to dietetic measures.

169. Pulmonary Embolism in Childhood.

ACCORDING to J. M. SMELLIE (*Arch. of Dis. in Childhood*, October, 1929, p. 328) pulmonary embolism in childhood is extremely rare; he reports a case which presents several unusual features. A boy, aged 9, who had always appeared to be healthy, died after an acute illness of only about nine hours' duration. The chief symptoms were shivering and cold, vomiting, and a yellowish discharge from the mouth and nostrils. At the necropsy a large, firm, ante-mortem clot of opaque, greyish-white colour was found firmly adherent only to the right auricular appendage, whence it extended through the right auricle, through the tricuspid valve, through the right ventricle and pulmonary valve into the pulmonary artery, finally terminating in each pulmonary artery just distal to the bifurcation. The thrombus lay entirely free in the artery; the terminal portion in the right artery had become dislodged, and formed an infarct in the lower lobe of the right lung. Many subepicardial petechial haemorrhages were found over the anterior and posterior aspects of the heart, but endocarditis was not present. Smellie remarks that the most important causes of thrombosis are changes in the composition of the blood and in the vessel walls, and mechanical factors causing a disturbance of the circulation. The last-named, though frequently met with (the cardiac thromboses in auricular fibrillation and myocardial failure), are most rare in children. Changes in the endocardium must therefore take first place, and these can only result from inflammation, and the necropsy findings in Smellie's case showed that the epicardium was the seat of a very early acute inflammation, just beginning to involve the myocardium. The most frequent cause of acute cardiac infection in childhood is acute rheumatism, and this infection may be more virulent and rapidly fatal than is generally recognized. Blumer has stated that all forms of thrombosis are exceedingly rare in rheumatic fever, and that cardiac thrombosis, except the form occurring with a complicating endocarditis and arterial thrombosis, is almost unknown. Smellie considers, however, that the infecting cause in the present case was the *Streptococcus rheumaticus*, though this cannot be definitely established, since no histological examinations were made.

170. Non-tuberculous Pneumothorax in Infants.

P. LEREBOULLET, M. LELONG, and R. EVEN (*Le Nourrisson*, September, 1929, p. 257) report two cases of this condition. A female infant had general convulsions and pneumonia at the age of 13 months; three months later she developed a sudden temperature of 103°F., with dyspnoea, rapid and shallow respiration, pallor, and cyanosis. The left lung was normal. The right lung gave no signs of dullness on percussion, but at the angle of the scapula a distant murmur was heard which was metallic in character; there were no rales. Twenty-four hours later there was tympanitic resonance of the right lung posteriorly, with amphoro-metallic breath sounds; anteriorly there was a tympanitic resonance, but no respiratory murmur. The left lung appeared normal posteriorly, but anteriorly there was tympanism with amphoro-metallic breath sounds which were much louder than on the right side and suggested a left pneumothorax. No rales were heard in either lung. Radiographic examination revealed the existence of a total right pneumothorax. The clinical signs disappeared in a few days, but it was fourteen weeks before the *x*-ray picture was normal. The cutaneous tuberculin reaction was negative throughout. In the second case *x*-ray examination of a male infant, 9 months old, who had a persistent cough, showed a total right pneumothorax, but there were no clinical signs; three months later the lung had almost recovered. Clinically the authors recognize two types, as evidenced in their cases—the acute and the latent, the latter being perhaps the more common. At this age period (under 2 years) the condition is less rare than a tuberculous pneumothorax. Pneumonia, broncho-pneumonia, pulmonary abscess, and whooping-cough were responsible for 32 of the 45 cases collected by the authors. Prognosis depends on the cause. If the pneumothorax remains dry, progressive recovery is the rule. The immediate treatment varies according to the symptoms. Oxygen is indicated if dyspnoea is marked, and puncture of the pleura if the pneumothorax is valvular, with cardiac tonics, such as adrenaline and camphor. Later treatment should be directed towards the cause and complications. A pyopneumothorax calls for surgical intervention, but the condition is nearly always fatal.

171. Egg Diet for Infants.

W. STOELTZNER (*Deut. med. Woch.*, January 3rd, 1930, p. 4) has considered the nourishment requirements of newborn children, especially those born prematurely and not ready for mother's milk, those who are unable to get mother's milk, and those with whom the mother's milk disagrees or is insufficient. Cow's milk contains nourishment suitable for a later developmental stage than human milk, and in view of the more rapid growth of the calf it is relatively poor in carbohydrates. The newly hatched chick is yet more developed than the newborn calf or newborn child, and the hen's egg contains nourishment suitable for the combined periods of both foetal life and breast-fed life. In view of these facts Stoeltzner comments on the method of the Finnish author Ylppö, and has devised a soup, composed of cow's milk, mondamin, "kinderzucker," and water, to a litre of which is added one fresh egg, the whole being then well stirred and passed through a sieve. This soup contains 2 per cent. protein, about 2½ per cent. fat, and 9 per cent. carbohydrate; it is found to give most satisfactory results in the three classes of infants referred to.

Obstetrics and Gynaecology.

172. Malignant Neoplasm in the Vaginal Scar after Total Hysterectomy.

ACCORDING to LAROYENNE and J. MARION (*Lyon Méd.*, November 24th, 1929, p. 617) the development of a malignant neoplasm in the cervical stump after subtotal hysterectomy is much more frequent than in the vaginal vault after panhysterectomy. The case is recorded of a woman, aged 52, who six years after abdominal total hysterectomy for myoma of the uterus complained of vaginal bleeding, and was found to have a projecting non-friable tumour in the roof of the vagina. It was removed by the abdominal route, and the patient, in spite of the appearance of a ureteric fistula, followed by pyonephrosis and nephrectomy, recovered. Microscopically the tumour was found to be a myoma with malignant metaplasia; eighteen months later there was clinical evidence that a secondary growth was present. No microscopical examination of the tumour removed at the first operation was carried out. Lucène has reported a case of malignant tumour appearing in the vaginal vault eleven years after total hysterectomy for adnexal inflammatory disease.

173. Treatment of Uterine Prolapse.

L. E. PHANEUF (*New England Journ. of Med.*, October 31st, 1929, p. 875) discusses various vaginal operations for uterine prolapse, and refers specially to the Watkins-Schauta-Wertheim interposition operation, which he has modified in certain details, employing it for patients whose uteri are normal or hypertrophied and where no pre-cancerous condition of the uterus is suspected. All interposition operations should be preceded by curetting and high amputation of the cervix if laceration, erosion, ectropion, or hypertrophy is present. The technique of the interposition operation is fully described. All patients were examined at the time of their discharge from hospital and again six weeks after the operation. Out of 148 cases 7 recurrences had been reported; five of these were classed as total failures, recurrence being due to the fact that the uteri were too atrophied for the operation to be beneficial. One failure was due to the too early absorption of the upper suture attaching the fundus to the upper angle of the vaginal denudation. These failures were permanently corrected by effecting a fixation of the interposed uterus to the anterior abdominal wall, using three linen sutures in each case. The mortality of the interposition operation was 2.7 per cent., but each of these cases had several operations. The author treats procidentia in young women during the child-bearing period by repairing the cervix, the anterior vaginal wall, and the perineum, shortening the utero-sacral ligaments, and performing a round ligament suspension of the uterus. In old women, where even an extensive vaginal operation is contraindicated, either a subtotal colpectomy (Le Fort operation) or the total colpectomy (Dujarier and Larget) is used. These operations ensure the minimum amount of post-operative shock and are followed by a comfortable convalescence.

174. Ventro-fixation and Ventro-suspension.

H. S. KENRICK (*New Zealand Med. Journ.*, October, 1929, p. 288) opposes the general employment of ventro-fixation and ventro-suspension, and considers that the particular advantages of these procedures are limited. Ventro-fixation should only be performed after the child-bearing age, with the exception of a few special conditions. If the uterus is small and atrophic it cannot be pulled up sufficiently high to perform a fixation, and, should this be attempted, the uterus will be fixed too low down on the abdominal wall, with consequent embarrassment of the bladder function. Ventro-fixation is also contraindicated in cases of extreme obesity. The objections to ventro-suspension are that the union may be drawn into such a long ligament that the displacement returns, and, secondly, the intestine may become twisted round the narrow band. In all ordinary cases of simple retroversion the author considers the operation of choice is the retroperitoneal modification of Gilliam's shortening of the round ligaments. If, however, all the details of technique of the ventro-fixation are carefully carried out on selected cases good results should be obtained.

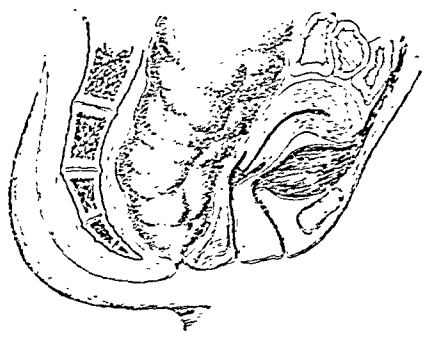
175. Uterine Developmental Abnormalities.

THE occurrence of double uterus, due to variations in the fusion of the Müllerian ducts, is probably more frequent than is generally suspected, and its frequency and importance may be underestimated. J. F. PUDDICOMBE (*Surg., Gynecol. and Obstet.*, December, 1929, p. 799) gives a partial review of the literature on this subject, together with a report of 19 cases. Falls believes that 1 per cent. of all uteri are bicornuate, and another writer estimates that 14 per cent. of all uterine anomalies are of this type. The distal ends of the Müllerian ducts, being in apposition in the genital cord and flanked by the mesonephric ducts, which exert pressure in a medial direction, fuse at the 20 to 30 mm. stage of the embryo and result in the unpaired "anlage" of the uterus and vagina. The remaining parts of the ducts lying at the cephalic end of the genital core persist in pairs and become the uterine tubes. During the twelfth to the fourteenth week of embryonic life the formerly approximated medial walls disappear and fusion is completed. Canalization takes place from below upwards, thus forming the potential cavities of the vagina and uterus, the process being completed between the twentieth and twenty-fourth weeks. Theories as to the cause of uterine duplication are varied, the most acceptable being that of Ancel and Villemin. Finding 25 cases with a vesico-rectal fold, and noting that these occurred only in females and were always accompanied by uterine duplication, they stated that this fold is vascular in origin, the segment from the upper rectum to the bladder being produced by a branch of the superior haemorrhoidal artery, the remaining portion, which extends to the sigmoid, being formed by a collateral branch of that vessel. Puddicombe believes that the etiology of bicornuate uterus probably lies in some mechanical obstruction preventing complete union of the paired ducts of Müller, and that such a uterus is liable to the same conditions as a single one more frequently than to its unique tendency to dysfunction. The author adds that in obstetrics the possibility of the presence of a dual organ and its potential dangers must be remembered if labour is extremely slow; if the foetal heart is irregular and rapid before labour begins; in all malpositions; and particularly in primiparae, and when there is a history of repeated abortions before the fourth month. Superfoetation may be due to a bicornuate, septate, or didelphys (complete doubling both externally and internally) uterus.

Pathology.

176. Laboratory Tests of B.C.G.

P. MAURIAC and E. AUBERTIN (*Journ. Path. Méd. de Bordeaux et du Sud-Ouest*, November 30th, 1929, p. 919) believe that the evidence of the innocuity of B.C.G. is almost irrefutable. They have experimented on a large number of laboratory animals to which various poisonous substances, such as phosphorus, thyroxine, uranium nitrate, and alcohol, had been administered for the purpose of lowering their vitality. Some animals also had had their pancreas removed to produce diabetes. None of these pathological states appeared to influence the virulence of B.C.G. A sufficient inoculation of the vaccine caused in these animals, as in healthy controls, local reactions (caseous nodules and adenitis) varying in severity with the dose employed, but without evidence of tuberculous lesion. In surviving animals the local lesion disappeared, with or without ulceration, as in normal animals. When the animals died others were inoculated with material from their local lesions, but the virulence of B.C.G. was not augmented, and it generally disappeared after the third, fourth, or fifth passage. The authors found that diabetes and intoxication with thyroxine or alcohol were not influenced by concomitant injection with B.C.G. Conversely, it appeared to aggravate the renal and hepatic degenerations produced by uranium and phosphorus. The authors recommend that B.C.G. should not be administered to a human patient who has a renal lesion; they believe that it is a strain of tubercle bacilli definitely and hereditarily attenuated, not only harmless *per se*, but unable (with the single exception mentioned) to influence independent pathological processes. They discuss at some length the few alleged cases of deaths following inoculation with B.C.G. that have been brought to their notice. While admitting that a period of even five years is too short to prove that there is no latent infection, they believe that the preliminary experiments have shown that the employment of this treatment should not be postponed indefinitely. They conclude, for their own part, that at the present time practitioners can and should practise with confidence preventive inoculation with B.C.G., at any rate in all cases where it appears difficult to avoid danger of tuberculous infection.



177. Spontaneous Tuberculosis in Guinea-pigs.

ACCORDING to H. A. REISMAN and ADELAIDE B. BAYLIS (*Journ. Lab. and Clin. Med.*, December, 1929, p. 205), the use, universally adopted, of guinea-pigs for the inoculation diagnosis of tuberculosis may lead to diagnostic errors, as it is possible that a pre-existing tuberculous infection may be present in the animals. Sewal found spontaneous tuberculosis in a notable number of laboratory guinea-pigs which had never been intentionally inoculated with tuberculosis; and Cooper and Petroff have demonstrated the presence of tubercle bacilli in the lymph nodes of 33 per cent. of normal guinea-pigs. The present authors record a series of experiments which they made along these lines on guinea-pigs, the results of which lead to the conclusion that tuberculosis may be present in apparently normal guinea-pigs, and that these animals may have a pre-existing tuberculous focus similar to that induced by inoculation; an intracutaneous tuberculin test will, however, reveal the presence of a tuberculous lesion. The authors point out the importance of this contingency in relation to the various laboratory investigations for detecting tuberculosis in human beings, and they advise that guinea-pigs of uncertain history should be tested with tuberculin before being employed for such purposes.

178. The Spinal Fluid in Poliomyelitis.

G. DE SIMONE (*La Clinica Pediatrica*, November, 1929, p. 1038) records eight cases of poliomyelitis in children aged from 6 months to 4 years in whom the meningeal reaction in the cerebro-spinal fluid was constant and in some instances well marked. The cytological reaction, when it was pronounced at the onset, subsequently showed a progressive decrease, but the globulin increase persisted for a considerable time. In some instances the meningeal reaction in the spinal fluid was accompanied by clinical symptoms of meningitis.

The Menace of the Overloaded Bowel

always present, easily becomes serious in women. It causes interference with the pelvic circulation and tends to produce congestion of the uterus, not infrequently followed by functional disorders, producing dysmenorrhœa, menorrhagia, and even inflammatory conditions.

AGAROL Brand Compound gives relief and frequently permanently restores the functional activity of the colon. One tablespoonful before retiring, gradually decreased as improvement takes place, is especially well adapted for the treatment of constipation in women, because of the gentle action of Agarol Brand Compound and absence of irritation from its use.

A liberal trial quantity at the disposal of physicians.

FRANCIS NEWBERY & SONS, LTD.
31-33, BANNER STREET,
LONDON, E.C.1

Prepared by WILLIAM R. WARNER & CO., INC.
Manufacturing Pharmacists Since 1856

Agarol Brand Compound is the *original* Mineral Oil—Agar-Agar Emulsion (with Phenolphthalein) and has these advantages:
Perfect emulsification; stability; pleasant taste without artificial flavouring; free from sugar, alkalies and alcohol; no oil leakage; no griping or pain; no nausea; not habit forming.

Simplicity is the keynote of Philips "Metalix-Portable"

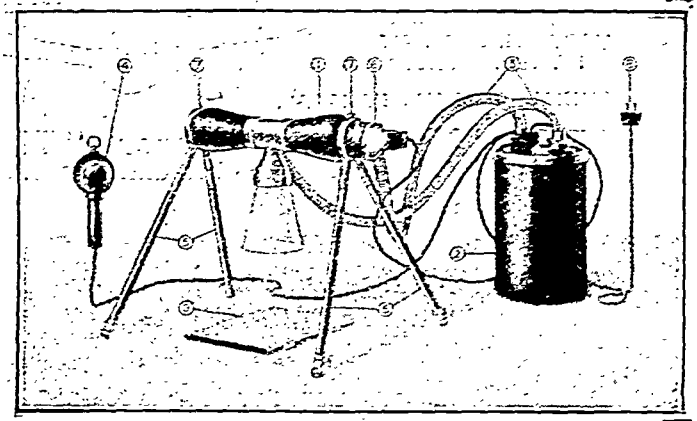
THE APPARATUS DESCRIBED

1. *Special "METALIX" X-ray tube 100% safe—complete X ray protection—absolutely shockproof. Nothing to give trouble.*

2. *High Tension transformer—fed from electric light—delivers correct voltage to X-ray tube.*

3. *Metal-clad shockproof cables, permanently attached to tube. Accommodated in sockets in the top of transformer.*

4. *Automatic time switch reading 0-15 seconds—controls exposure. Connected by one of the only two flexible leads with which the apparatus is provided.*



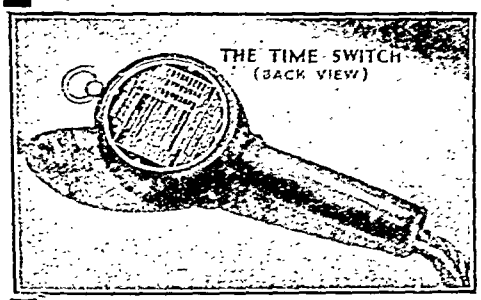
5. *Telescopic legs—enable tube to be adjusted to convenient height. Fold beside tube when not in use.*

6. *Forced draught cooling attachment—permits of apparatus being used for visual examination. Can be disconnected for ordinary use.*

7. *Locking screw—one at each end of the tube. Enables angle of the tube to be adjusted. If required X-ray beam can be directed upwards.*

8. *Plug connection to electric light supply. On direct current circuits to output side of small converter. Simple means are available for dealing with odd voltages.*

9. *Cassette or film holder. Apparatus will cover all standard size X-ray films.*



The once prophetic notion of an "X-ray camera" has at last been successfully exploited.

Incredibly simple, 100 per cent. safe, this is the outfit for which the world was waiting. PHILIPS "METALIX-PORTABLE" puts radio-diagnosis on an entirely new footing. There has been nothing like it.

To the busy practitioner it will particularly appeal. You need no previous experience—only a source of current supply.

Prices:—6 in. 4/6, 8 in. 6/-, 11 in. 8/3.

Stocked by all the leading Chemists and Druggists; Boots 500 branches; Timothy White Ltd.; Taylors Drug Stores; and Parkes Chemist Ltd.

FOR DEAFNESS
Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf.
7. It is helpful for conversation, music wireless, home, office, public work, and sports.

"ARDENTE" STETHOSCOPE.
Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.

MEDICAL REPORTS.
Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

Accurate Arterial Pressure Readings

For visiting purposes the TYCOS Portable Sphygmomanometer amply fulfils the Physician's needs. Although one of the most delicate and accurate instruments of the medical man's equipment, the portable type as illustrated can be carried without fear of breakage. There is no glass tubing to break, no mercury to spill, and the readings can be verified at a glance by comparing the relation of the hand to the immovable zero.

Care should be taken to avoid close imitations. Look for the trade mark 'TYCOS' engraved on the dial of every genuine instrument.

Obtainable from all reputable Instrument Dealers.

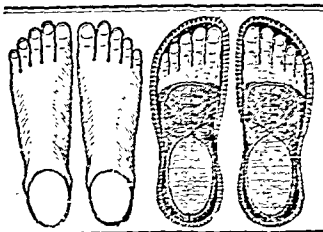
Vapo-Cresolene Est. 1879

Sold by all Chemists



Write for descriptive Booklet No. 39B.

ASTHMA

There are certain types of chronic asthmatics who require relief of their paroxysms. While adrenaline is generally effective, it must be given hypodermically, and its action is short lived. Vapo-Cresolene (specially prepared cresols of coal tar) vaporized in the bedroom at night will give the desired relief. The patient is not disturbed as he breathes the medicated air of the bedroom.
This antiseptic vapour is particularly effective in bronchial ailments accompanied with cough and difficult breathing—as bronchitis, whooping cough, spasmodic croup.

EATAN

Pronounced E-TAN

NEURO TONIC
NUTRITIVE
DIGESTIVE
RECUPERATIVE

A great advance on Meat Juices, Jellies, Essences, etc., particularly in extreme Weakness, Gastritis, Fever, Debility, after Operations, Tuberculosis, etc. Very palatable. Non-irritant. Dr. Haff, after long experience in the transplantation of glands in deficiency diseases, conceived and produced the hydrolysates contained in Eatan for the positive regeneration of the body tissues, when the natural processes of metabolism fail to function normally.
A host of testimony from the medical profession and numerous clinical tests have definitely established Eatan as a unique restorative beverage for invalids.
Issued in 2/6, 4/-, and 10/8 bottles.
Special Terms to Hospitals.
Test sample and literature sent post free on application to:

CHEADLE ROYAL,

CHEADLE, CHESHIRE.

This registered Hospital for MENTAL DISEASES, with its seaside branch Glan-y-Don, Colwyn Bay, is for the treatment and care of PRIVATE PATIENTS of the UPPER and MIDDLE CLASSES. Voluntary Boarders received.

For terms, etc., apply to the Medical Superintendent, J. A. C. ROY, M.B., who may also be seen in Manchester by appointment.

Telephone: 481 GATLEY.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS,

NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one or the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.

HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

Tel.: 64117. *For terms, etc., apply to the Medical Superintendent.*

Salary at the rate of £100 per annum first six months, £130 per annum second six months, plus board, lodging, washing, and certain fees as perquisites.

Applications, with one copy of three recent testimonials, to be sent to the undersigned immediately.

C. E. CHAPMAN, Secretary.

West Middlesex Hospital,

ISLEWORTH.

Wanted on six months' engagement, with prospects of permanency, a MEDICAL (gentleman) ASSISTANT to the Medical Officer. Salary at the rate of £250 per annum, with residential emoluments. Apply immediately to the Clerk to the Guardians, Toolands House, 34, Twickenham Road, Isleworth, Middlesex.

The Royal Eye and Ear Hospital,

BRADFORD.

Wanted JUNIOR HOUSE SURGEON, male. Salary £150, with board, residence, and laundry.

Applications, stating qualifications, age, etc., with copies of recent testimonials, to be forwarded to the undersigned.

F. BRIGGS, Secretary-Supt.

County Council of Durham.

DEPUTY COUNTY MEDICAL OFFICER OF HEALTH.

The County Health Committee invite applications for the appointment of a Deputy County Medical Officer of Health at a commencing salary of £1,000, rising by annual increments of £50 to £1,200 per annum. Reasonable travelling and out-of-pocket expenses will be paid by the County Council.

Applicants must be duly registered Medical Practitioners holding a degree or diploma in Public Health, and the gentleman appointed will be required to devote the whole of his time to the duties of the office and to reside in the City of Durham or other approved centre.

He will be required to undertake any duties required of him by the Council bearing on the health and medical services of the county.

He will be required to act under the administrative control of, and to be responsible to, the County Medical Officer of Health for his duties.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and to a medical examination as required by the Council for the purposes of the Act, and the statutory contributions to the Superannuation Fund under that Act will be deducted from the salary.

Applications, marked "Deputy County Medical Officer," together with copies of not more than three recent testimonials, must be sent to the County Medical Officer, Shire Hall, Durham, not later than February 19th.

HAROLD JEVONS,
Clerk of the County Council.
Shire Hall, Durham, Feb. 3rd, 1930.

Derbyshire Education Committee

ASSISTANT SCHOOL MEDICAL OFFICER (Male).

The Derbyshire Education Committee require the services of an Assistant School Medical Officer (male) at a salary of £600, rising by annual increments of £25 to £700 per annum.

The candidate must be a registered Medical Practitioner of at least three years' standing. The duties will include work under the Maternity and Child Welfare Service. Experience in this work and in the administration of anæsthetics is essential.

The officer appointed will not be allowed to engage in private or consulting practice, but will be required to devote his whole time to the duties of the office, and will act under the direction of the School Medical Officer.

Forms of application may be obtained from the undersigned, to whom they should be returned completed, together with copies of not more than three recent testimonials, on or before Monday, February 24th, endorsed "Assistant School Medical Officer."

The appointment will be determinable by three months' notice on either side.

January, 1930.

City of Bradford.

MUNICIPAL GENERAL HOSPITAL, ST. LUKE'S.

HOUSE PHYSICIANS and HOUSE SURGEONS required. Salary in each case £200 per annum, with board and lodgings.

These appointments are for six months, renewable for a further period of six months.

Application forms may be obtained from the Medical Officer of Health, Town Hall, Bradford, and should be returned to him not later than February 28th.

N. L. FLEMING,
Town Hall, Town Clerk.
Bradford.
February 5th, 1930.

Parish of Portsmouth.

THIRD ASSISTANT RESIDENT MEDICAL OFFICER.

The Guardians of the above-named Parish invite applications for the appointment of Third Assistant Resident Medical Officer for SAINT MARY'S HOSPITAL, INSTITUTION, AND CHILDREN'S HOME.

The appointment will be made for a period of not less than one year, and will be subject to one month's notice on either side. Salary £250 per annum, with furnished apartments, rations, and all other allowances.

The appointment will be subject to the provisions of the Poor Law Officers Superannuation Act, 1896, for which purpose the value of the emoluments has been fixed at £125 per annum.

Candidates must be single gentlemen, duly registered, and possessing the qualifications required by the Orders of the Ministry of Health, and preference will be given to candidates having a knowledge of the treatment of Mental Diseases.

A Resident Medical Superintendent is in attendance.

Applications to be made on printed forms, which may be obtained at the Guardians' Offices, 1, St. Michael's Road, Portsmouth, and must be returned to me, accompanied by not more than three recent testimonials, and description of diplomas, certificates of degrees, licences, and other instruments held by the candidate, by 10 a.m. on Monday, February 24th.

Selected candidates will have notice to attend, and third-class railway fare and reasonable personal expenses will be allowed.

By Order,
W. E. GODFREY,
Feb. 7th, 1930. Clerk to the Guardians.

County Borough of Dewsbury.

DEPUTY SCHOOL MEDICAL OFFICER AND DEPUTY MEDICAL OFFICER OF HEALTH.

Applications are invited from duly qualified and registered Medical Practitioners (men or women) for the post of Deputy School Medical Officer and Deputy Medical Officer of Health (Tuberculosis and Child Welfare).

Applicants should have had at least three years' experience since qualification. Experience in Eye work and Refractions is essential. The possession of the D.P.H., and previous experience in School Medical Inspections and the work of a School Clinic, and in Tuberculosis and Child Welfare, will be considered important additional qualifications.

The inclusive salary will be at the rate of £600 per annum. Particulars of the duties and conditions of appointment, together with the application forms, may be obtained from Dr. R. M. GALLOWAY, Medical Officer of Health, Market Place, Dewsbury, to whom all applications, accompanied by copies of not more than three recent testimonials, should be returned, endorsed "Deputy Medical Officer of Health," not later than Friday, February 28th.

JUNIOR HOUSE MEDICAL OFFICER (male) required. The appointment, which will be for six calendar months, is approved by the University of London for the purpose of the M.D. examination. Salary at the rate of £100 per annum, with board, residence, and laundry.

Applications, with testimonials, to—

F. J. J. STACEY, Secretary.

Birmingham and Midland HOSPITAL FOR WOMEN.

HOUSE SURGEON (man or woman) wanted for six months from April 1st next. Salary to be at the rate of £75 per annum. Applications, with copies of testimonials, to be sent to Mr. H. C. ASTON, 45, Newhall Street, not later than March 1st.

Kent County Council.

ASSISTANT MEDICAL OFFICER (MATERNITY AND CHILD WELFARE).

The Kent County Council invite applications for the post of an Assistant Medical Officer (female). Salary £600 per annum, increasing by £12 10s. increments to £650. Candidates should be not more than 40 years of age.

The person appointed will be required to devote her whole time to the duties of the office, and will be under the administrative control and supervision of the County Medical Officer.

The duties will mainly consist of work in connection with the maternity and child welfare scheme, but will include any other duties allotted to the officer as coming within the purview of the County Health Department.

Preference will be given to candidates who have had special experience in connection with maternity work, and the Diploma of Public Health is desirable.

The appointment is subject to the approval of the Ministry of Health and also to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and will be terminable by three months' notice on either side. The person appointed will be required to pass a medical examination as to physical fitness.

Applications, stating age, qualifications, training, and full particulars of past experience, and accompanied by copies of three testimonials, should be submitted to Dr. A. GREENWOOD, County Medical Officer, Sessions House, Maidstone, not later than February 28th.

No official form of application will be issued, and canvassing will be considered a disqualification.

ALFRED GREENWOOD, M.D., *Sessions House, Maidstone. February 10th, 1930.* *County Medical Officer.*

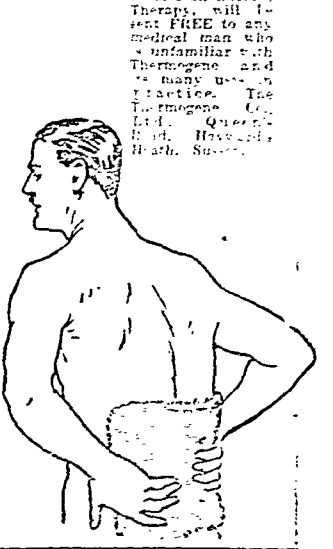
The Relief of "Rheumatic" Pains



Dr. Guntzburg, the Medical Superintendent of the Physiotherapeutic Institute of Antwerp, states that in practically all so-called "rheumatic" cases a pronounced degree of peripheral circulatory failure is symptomatic; and he says that the skin condition is "the immediate factor in the production of rheumatic pains." This is in accord with the emphasis laid at the recent Bath Conference on the part played by damp and cold in promoting neuritis and fibrositis.

Thermogene relieves pain by hastening the skin circulation, and so helping the removal of irritating waste products and the re-oxygenation of de-oxydised tissues.

The time to use Thermogene is when the very first twinge is felt. By its timely employment many an attack may be warded off.

Thermogene is a carefully prepared pure cotton wadding, remarkably soft and fleecy, freed from dust and other impurities, and impregnated with skin-stimulating vegetable essences.

A full-size box of Thermogene, with an interesting booklet on Surface Therapy, will be sent FREE to any medical man who is unfamiliar with Thermogene and its many uses in practice. The Thermogene Co. Ltd., Queen's Rd., Haywards Heath, Sussex.

THERMOGENE

MEDICATED WADDING

FELAMINE

SANDOZ

Felamine, an association of the most powerful cholagogue—pure crystallised cholic acid—and the classical biliary disinfectant—hexamine, provides a rational and effective treatment of biliary lithiasis, cholangitis, hepatitis, icterus, and all the symptoms of biliary insufficiency.

Felamine contains no accessory drugs. The cholagogic active principle (cholic acid) is present in an absolutely pure state, free from useless and harmful bile substances.

Indications.

Cholangitis, Cholecystitis, Hepatic Insufficiency, Hepatic Congestion, Jaundice, Chronic Constipation.

Felamine is supplied in Bottles of 50 and 250 Tablets at **5**/- *and* **20**/-

is prepared under and complies with
The THERAPEUTIC SUBSTANCES (CATGUT) REGULATIONS, 1929.

Licence No. 37

"Chorda" Catgut is supplied on a glass reel in a specially sealed carton.

In boxes of 3 cartons - 4/6 per box.
In boxes of 12 cartons - 16/- per box.

All sizes 6/0 to 6 in plain or hardened Catgut.

When ordering specify "CHORDA" Catgut.

Obtainable from

Allen & Hanburys Ltd., 48, Wigmore St., LONDON, W.1
and from all the Leading Surgical Equipment Houses.

ASPIRIN COMPOUNDS and RHEUMATIC AFFECTIONS

We are the Introducers and Actual Manufacturers of the following:

"MAGISAL"

PROMPT IN ACTION AS BEING A SOLUBLE SALT (1 in 12 AGAINST ASPIRIN 1 in 400).

"TYLCALSIN"

A further Soluble Salt

FOR USE ORALLY OR INTRAVENOUSLY IN RHEUMATIC AFFECTIONS AND OF VALUE IN CATARRH, NEURALGIA, AND FOR GENERAL RELIEF OF PAIN.

Bots. of 20 2/6; 100 11/6.

"SEDASPRIN"

A compound of Aspirin and Bromine

CONTAINING 30.86% BROMINE IN 5-GRAIN TABLETS. OF VALUE IN ALL FORMS OF NERVE TROUBLE, AND WHEREVER THE COMBINED QUALITIES OF ASPIRIN AND BROMIDE ARE INDICATED.

Bots. of 25 2/6; 100 7/6.

"PHENYL-SEDASPRIN"

A NEW COMPOUND OF THE SALOL TYPE EMBODYING THE THERAPEUTIC EFFECTS OF BROMINE, ASPIRIN, AND PHENOL.

Bots. of 25 3/-.

"TYLLITHIN"

A very Soluble Salt of Aspirin

FOR USE PER OS AS AN ANTI-RHEUMATIC AND INFLUENZA SPECIFIC, AND OF VALUE IN NEURALGIA, GOUT, AND AS A GENERAL ANALGESIC.

Bots. of 20 2/6; 100 11/6.

"ASPRIODINE"

A compound of Aspirin and Iodine

CONTAINING 41.47% IODINE IN 5-GRAIN TABLETS. OF DECIDED VALUE IN RHEUMATIC AFFECTIONS AND ARTERIO-SCLEROSIS.

Bots. of 25 2/6; 100 7/6.

"PHENYL-ASPRIODINE"

EMBODIES THE ACTIVITIES OF IODINE, ASPIRIN, AND PHENOL, AN INTESTINAL AND URINARY ANTISEPTIC.

Bots. of 25 3/-.

"METHYL-ASPRIODINE"

THE NEW ANTI-RHEUMATIC FOR INUNCTION

BALM 2/6. LINIMENT 2/6.

Literature and samples of any of the above supplied on request

SAUNDERS

CHRISTOPHER: MINOR SURGERY

"THE HOUSE SURGEON WILL FIND IT INVALUABLE"

"This is a very good book. Its arrangement follows the usual lines except for the welcome addition of a long chapter designed for "The Surgical Intern." This is full of sound advice which may be read with profit, not only by the house surgeon, but also by his chief, and is mostly applicable to residents in our own hospitals. . . . The book is admirably printed on excellent paper and the illustrations are superb. The consulting surgeon and the practitioner will find much to interest them, while the house surgeon will find it invaluable."—THE LANCET.

By FREDERICK CHRISTOPHER, M.D., F.A.C.S., Associate in Surgery, Northwestern University Medical School, Chicago. With a foreword by ALLEN B. KANAVEL, M.D., F.A.C.S., Professor of Surgery, Northwestern University Medical School. Octavo of 694 pages, with over 600 illustrations on 455 figures. Cloth, 36s. net.

JACKSON & COATES: NOSE, THROAT, EAR

"A FAITHFUL PICTURE OF THE BEST MODERN PRACTICE"

"It would be impossible to appraise the merits of all the articles, so varied and so diverse, but as they must be taken collectively, it may be said that on the whole they maintain a high level and give a faithful picture of the best modern practice, with copious illustrations and admirable coloured plates."—BRITISH MEDICAL JOURNAL.

Edited by CHEVALIER JACKSON, M.D., Sc.D., LL.D., F.A.C.S., Professor of Bronchoscopy and Esophagoscopy, University of Pennsylvania and Jefferson Medical College; and GEORGE M. COATES, M.D., A.B., F.A.C.S., Professor of Otology, University of Pennsylvania Graduate School of Medicine. Assisted by CHEVALIER L. JACKSON, A.B., M.D., Assistant in Bronchoscopy and Esophagoscopy, Graduate School of Medicine, University of Pennsylvania. Cloth, 60s. net.

WECHSLER: THE NEUROSES

"INTERESTING AND UNDERSTANDABLE"

"Professor Wechsler believes that at the present time psycho-pathology offers the best understanding of the neuroses, and he has written his book in a manner which is interesting and understandable. It should not fail to make an appeal to students and practitioners, for whom it is primarily intended."—EDINBURGH MEDICAL JOURNAL.

By ISRAEL S. WECHSLER, M.D., Associate Professor of Clinical Neurology, Columbia University, New York City. Octavo of 339 pages. Cloth, 18s. net.

GRANGER: PHYSICAL THERAPEUTIC TECHNIC

"PLENTIFULLY INTERSPERSED WITH PRACTICAL HINTS"

"The whole book is plentifully interspersed with practical hints on technique, helpful both to the beginner and to the specialist who has developed his own technique, but who is always open to improvements or suggestions."—JOURNAL OF THE MEDICAL ASSOCIATION OF SOUTH AFRICA (B.M.A.)

By FRANK B. GRANGER, A.B., M.D., Late Physician-in-Chief, Department of Physical Therapeutics, Boston City Hospital. Octavo of 417 pages, with 135 illustrations. Cloth, 30s. net.

BOLDUAN: PUBLIC HEALTH AND HYGIENE

"PRESENTS THE SUBJECT IN A MOST INTERESTING WAY"

"This is essentially a manual for students. It does not go into details as much as most elementary works on Public Health and Hygiene, but it presents the subject in an unconventional and most interesting way. . . . The book is copiously supplied with excellent illustrations and diagrams."—IRISH JOURNAL OF MEDICAL SCIENCE.

By CHARLES F. BOLDUAN, M.D., Director, Bureau of Health Education, Department of Health, City of New York. 12mo. of 312 pages, illustrated. Cloth, 12s. 6d. net.

VOLUME OF THE BLOOD AND PLASMA

A NEW MAYO CLINIC MONOGRAPH

This new work discusses the status of blood volume studies, reviews the literature on the experimental and clinical work carried out by the dye method, considers the criticisms and suggestions offered by various investigators as to the results of their experience with this method, and presents also the results of the authors' own clinical studies with this method, extending over a period of six years and involving more than 1,000 determinations in a series of more than 350 clinical cases.

By LEONARD G. ROWNTREE, M.D., and GEORGE E. BROWN, M.D., Division of Medicine, The Mayo Clinic and the Mayo Foundation, Rochester, Minn. 12mo. of 219 pages, illustrated. Cloth, 14s. net.

W. B. SAUNDERS COMPANY LTD. 9, Henrietta Street LONDON, W.C.2

From EDWARD ARNOLD & CO.'S List

MAN'S PLACE AMONG THE MAMMALS

By FREDERIC WOOD JONES, F.R.S., Professor of Anatomy in the University of Melbourne; formerly Professor of Anatomy in the University of London.

xii + 372 pp., 160 Illus. 21s. net.

"A brilliantly-written book, one that will serve a great and useful purpose in stimulating profitable discussion and further research."—SIR A. KEITH in *Nature*.

THE MATRIX OF THE MIND

By F. WOOD JONES, F.R.S., and S. D. PORTEUS, Professor of Clinical Psychology, University of Hawaii.

viii + 424 pp. 80 Illus. 21s. net.

"Learned, lively, and interesting. . . An alert and stimulating performance, on which the authors are to be congratulated."—*Times*.

PRINCIPLES OF BACTERIOLOGY AND IMMUNITY

By

W. W. C. TOPLEY, M.A., B.Ch., M.R.C.S., F.R.C.P., Professor of Bacteriology and Immunology; and

G. S. WILSON, M.D., B.S., D.P.H., Reader in Bacteriology and Immunology, in the London School of Hygiene and Tropical Medicine.

"The book is admirable in its conception and excellent in its execution, and should prove of the greatest service not only to the post-graduate student of this subject, but to bacteriologists in general."—*British Med. Journ.*

"This book, we feel sure, will receive a cordial welcome from all practising bacteriologists and teachers of this subject. There is much to commend, and little to criticize."—*Lancet*.

"The authors are to be congratulated both on the substance and the method of presentation of these admirable volumes."—*Times*.

GARROD & BATTEN'S DISEASES OF CHILDREN

New Second Edition, with Contributions by 36 Authors. Edited by HUGH THURSFIELD, D.M., M.A., F.R.C.P., and DONALD PATERSON, M.D., F.R.C.P., Physicians to the Hospital for Sick Children, Great Ormond St.

xii + 1,106 pp., 205 Illus. 45s. net.

"This is essentially a book for the practitioner, and it should be destined to become his constant companion for many years to come."—*Practitioner*.

NEW (SEVENTH) EDITION.

A MANUAL OF PHARMACOLOGY

By WALTER E. DIXON, M.A., B.Sc., F.R.S., Examiner in Pharmacology in the Universities of London, Oxford, and Cambridge.

xii + 486 pp., 95 diag. 18s. net.

LONDON: EDWARD ARNOLD & CO., 41 & 43, MADDOX STREET, W.1.

DISEASES OF THE HEART

With chapters on the Ink Polygraph, Clinical Electro-Cardiography, X-Ray Examination, and Anæsthesia in relation to Cardio-Vascular Affections.

By FREDERICK W. PRICE, M.D., F.R.S.(Edin.), Physician to the National Hospital for Diseases of the Heart; Consulting Physician to the Royal Northern Hospital, London.

Demy 8vo. Pp. 534. With 249 text figures, including 32 sphygmograms, 92 polygraphic tracings, and 87 electro-cardiograms.

NEW SECOND EDITION, 21s. net.

"By great care and by the use of an amazing amount of material, he has accomplished what many readers have been waiting for, giving us a complete account of the diagnosis, prognosis, and treatment of heart diseases by modern methods in association with all the invaluable teaching bequeathed to us by the older masters of clinical observations."—LANCET.

"The most valuable and comprehensive guide to the study of Cardiology with which we are acquainted."—NEW YORK MEDICAL JOURNAL AND RECORD.

"We think that most of our readers engaged in general practice will find this work extremely useful."—THE JOURNAL OF CLINICAL RESEARCH.

"In our opinion the book is indisputably the most authoritative contribution to Cardiology of our time."—FRANCO-BRITISH MEDICAL REVIEW.

"A book which we believe is destined to remain the standard work on Cardiology for many years to come."—AMERICAN MEDICINE.

"The second edition of this popular work on heart disease bears evidence of thorough revision, while the essentially clinical standpoint of the writer is maintained."—EDINBURGH MEDICAL JOURNAL.

"It may be said at once that the book adequately fulfils the purpose it has in view and is a perfectly sound, lucid, and reliable guide."—NEWCASTLE MEDICAL JOURNAL.

"Well-written, concise, and complete, containing a wealth of practical information. Obviously based upon the author's own experience and investigative work."—SURGERY, GYNECOLOGY, AND OBSTETRICS (Official Journal of the American College of Surgeons).

"Dr. Price is to be congratulated again on the reappearance in its second edition of his distinguished contribution to the increasingly important subject of Cardiology."—THE CANADIAN JOURNAL OF MEDICINE AND SURGERY.

OXFORD UNIVERSITY PRESS, Amen House, Warwick Square, London, E.C.4.

THE CLINICAL JOURNAL. 6d.

An Illustrated Weekly Record of CLINICAL MEDICINE and SURGERY. 6d.

Including a Section on MEDICAL PROGRESS dealing concisely with the most important advances.

". . . my weekly perusal of the 'Clinical Journal' was a very important factor in my medical education."—SIR THOMAS HORDER.

Special Leaflet, with selected list of articles and other details, on application.

ANNUAL SUBSCRIPTION (commencing at any date), 26s.; Six Months, 13s. 6d.; Three Months, 7s., post free.

London: H. K. LEWIS & CO. Ltd., 136, Gower Street, and 24, Gower Place, W.C.1.

"Should be in the possession of every medical man."—*Glasgow Medical Journal*.

URINARY SURGERY

A Handbook for the General Practitioner

By W. K. IRWIN, M.D., F.R.C.S., Assistant Surgeon, St. Paul's Hospital for Genito-Urinary Diseases.

"Clearly written . . . furnishes the practitioner with information of great practical value in his everyday work."—*British Medical Journal*.

SECOND EDITION. Revised and Enlarged. Price 10s. 6d. (postage 6d.)

BAILLIÈRE, TINDALL & COX, 7 & 8, Henrietta St., London, W.C.2.

176 Illus. (some in Colour). 42s., post. 1s.

Matthes' Text-Book of Differential Diagnosis of Internal Medicine

Translated from the Fourth German Edition, with extensive alterations, by I. W. HELD, M.D., and M. H. GROSS, M.D.

"It is very readable, and may be recommended to students and practitioners."—PRACTITIONER.

LONDON: J. & A. CHURCHILL, 40, Gloucester Place, Portman Square, W.1.

BAILLIÈRE, TINDALL & COX

PROTOZOOLOGY: A Manual for Medical Men

By JOHN GORDON THOMSON, M.A., M.B., Ch.B., Director, Department of Protozoology, London School of Tropical Medicine; and ANDREW ROBERTSON, M.B., Ch.B., Lecturer in the Department of Protozoology, London School of Tropical Medicine.

¶ "*This work occupies a place of its own. It is written expressly for medical men and deals with those protozoa which are human parasites.*"—LANCET.

Size 10"×7½". Pp. xvi+376. With 4 Coloured Plates and 220 Illustrations. Price 30s. Postage: Inland 9d.; Abroad 1s.

MUSKENS' EPILEPSY: Comparative, Pathogenesis, Symptoms and Treatment

Foreword by SIR CHARLES SHERRINGTON, F.R.S.

¶ "*. . . . an outstanding contribution to the experimental study of epilepsy . . . . a sound and well-balanced discussion of its clinical aspects which is well worth reading.*"—LANCET.

Royal 8vo. Pp. xiv+435. With 64 Illustrations. Price 27s. 6d. Postage: Inland 9d.: Abroad 1s. 2d.
English Edition. Revised and brought up to date.

HELMINTHOLOGY: Medical and Veterinary

By H. A. BAYLIS, M.A., D.Sc., Assistant Keeper, Department of Zoology, British Museum (Natural History).

¶ *This work gives a full account of the numerous species of worms parasitic in man and the domestic animals.*

Size 9½"×6½". Pp. xii+304. With 200 Illustrations. Price 30s. Postage: Inland 9d.; Abroad 1s.

CARE OF CHILDREN IN THE TROPICS

By ERIC C. SPAAR, B.A., M.D., B.S.Lond., M.R.C.P., Fellow of the Royal Society of Medicine; Physician, General Hospital, Colombo; Late Physician, Children's Fever Hospital, Hampstead, London; Clinical Assistant, Great Ormond Street Hospital for Sick Children, London; and Lecturer on Diseases of Children at the Ceylon Medical College.

Pp. xiv+265. Price 7s. 6d. Postage: Inland 6d.; Abroad 8d.

IMMUNITY IN INFECTIOUS DISEASES

By A. BESREDKA, Professor at l'Institute Pasteur. Authorised translation by HERBERT CHILD, M.R.C.S.Eng., Late Hon. Surgeon, French Red Cross; Capt., R.A.M.C. (Ty.).

Size 8"×5". Pp. vi+320. Price 18s. Postage 8d.

HABITUAL CONSTIPATION AND ITS TREATMENT

By M. H. BURNIER, M.D.Lausanne, M.R.C.S.Eng., L.R.C.P.Lond.

¶ "*This is a useful monograph written with the view of introducing a new method of applying internal massage to the rectum. Chronic constipation is such a bane that the author's suggestions are well worth a trial.*"—MEDICAL OFFICER.

Pp. x+70. Price 3s. 6d. Postage 3d.

SLEEP and the Treatment of its Disorders

By R. D. GILLESPIE, M.D., D.P.M., Physician and Lecturer in Psychological Medicine, Guy's Hospital, London.

¶ "*Supplies a definite demand and gives an entirely up-to-date presentation of the subject. The book may be read with pleasure and profit.*"—LANCET.

Size 7½"×5". Pp. viii+267. With 5 Figures. Price 7s. 6d. Postage 6d.

BLOODGROUPING IN RELATION TO LEGAL AND CLINICAL MEDICINE

By LAWRENCE H. SNYDER, M.D., North Carolina State College. A thorough discussion of transfusion as well as of more recent applications.

Size 9"×6". Pp. xii+154. 28 Figures. Price 22s. 6d. Postage: Inland 6d.; Abroad 8d.

SELECTED READINGS in PATHOLOGY: from Hippocrates to Virchow

By ESMOND R. LONG, Professor of Pathology, University of Chicago.

Size 6½"×9½". Pp. xiv+301. 25 Plate Illustrations. Price 18s. Postage: Inland 6d.; Abroad 8d.

CORONARY THROMBOSIS: Its various Clinical Features

By SAMUEL A. LEVINE, M.D. Reviews various clinical features of coronary thrombosis, including electrocardiographic change, typical events of acute attacks, atypical forms and complications, and therapeutics.

Size 10½"×6½". Pp. viii+178. One Coloured Plate. Price 13s. 6d. Postage: Inland 6d.; Abroad 8d.

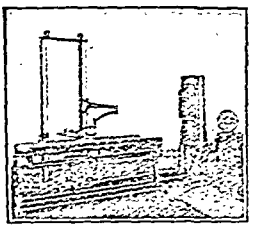
Radiography Made Safe

with the Victor Shock-Proof X-Ray Unit



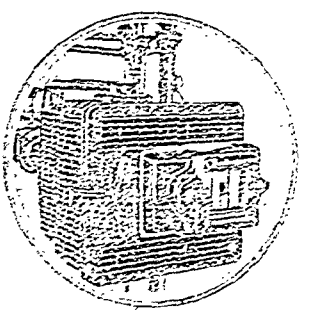
It's Oil Immersed

Angular Radiography
A crank and worm-gear arrangement facilitates tilting the table from either end.

Angular Fluoroscopy
Tube head lowered and swung under table, also revolved on its axis to direct the rays upward. Note how conveniently the fluoroscopic screen is brought into position.

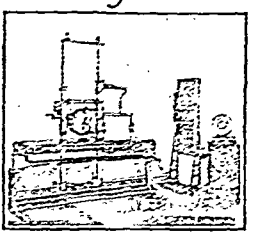
Horizontal Fluoroscopy from Under the Table
Observe the extension arm attached for operating the shutters and manipulating the tube head. The fluoroscopic screen and tube head move in unison.

Other Features



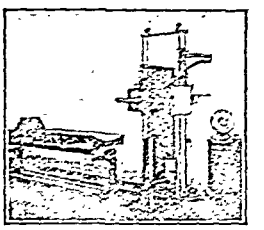
100% electrically safe. Compact.
Silent operation. Self-contained.
Greater Flexibility.
Increased diagnostic range.
Eliminates overhead system.
Longer tube life.
Same tube used over and under table.
Not affected by altitude or humidity.

THEY said it couldn't be done. To eliminate *all* danger of shock from X-ray apparatus does seem impossible. Yet Victor engineers have succeeded.

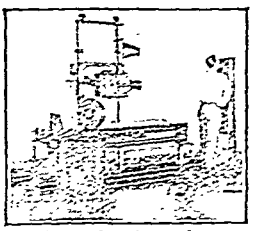


The secret of the Victor Shock-Proof X-Ray Unit, as you will see from study of the illustration, lies in the tube head. Both X-ray tube and high tension transformer, *immersed in oil*, are sealed inside this container. Completely insulated, the high tension current that has made X-ray apparatus dangerous, is kept where no one can come in touch with it.

Handle any part of this Victor Unit while in operation. There is no possibility of shock. Scientific publications the world over are proclaiming this one of the most remarkable achievements of recent years. Truly this unit represents, as they say, the most important development in roentgenology since the Coolidge tube itself.



May we send you a folder illustrating and describing this remarkable unit?



Close-up of tube head of Victor Shock-Proof X-Ray Unit in which both the X-ray tube and high tension transformer are mounted in oil, completely insulated and sealed, thus confining all high voltages within this head.

Fluoroscopy Crosswise the Table
Offers new possibilities in routine X-ray diagnosis. The tube head may also be adjusted angularly for this purpose. Thus the tube is adjusted to the patient rather than the patient to the tube.

Vertical Fluoroscopy
The tube head is behind the vertical fluoroscope. Note how the fluoroscopic screen swings into its normal position. The tube head and screen move in unison.

Vertical Radiography
A cassette tunnel is mounted on the back of the vertical fluoroscope. A vertical stereo unit (motor operated) is provided on the tube head carriage.

Other Features

Introduces a new principle of control.
Consistent results.
Complete diagnostic service.
Unit construction permits variation according to specialty.
Minimizes danger around ether, as when setting fractures, etc.
Few mistakes—longer tube life.

CHANGE OF ADDRESS FROM FEBRUARY 24

The need for increased office and display room accommodation has necessitated our moving to larger quarters. Not only will this permit a more adequate demonstration of Victor products, but the greater facilities will aid in giving that type of service which has become associated with the name of Victor.

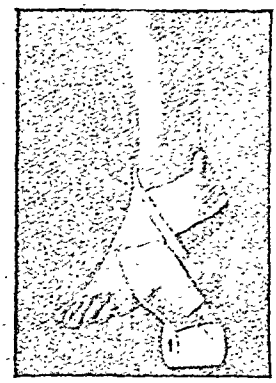
INTRODUCING

Elastoplast

ELASTIC PLASTER

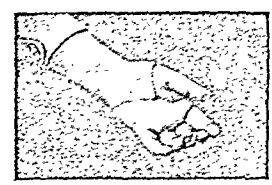
A NEW AND HELPFUL PRODUCT for the MEDICAL PROFESSION



Elastoplast
Application for Varicose Veins.

ELASTOPLAST comes to aid you in your daily work. It represents the greatest advance in surgical dressings technique that has been discovered for many years. ELASTOPLAST is an entirely new product—a specially woven, resilient material, covered with an antiseptic, non-irritant adhesive. It can be instantly applied, adheres firmly, and will remain in situ for any length of time, without creasing, yet allows perfect mobility. It is easily removed and can be used several times.

ELASTOPLAST BANDAGES are manufactured in two styles, plain and ventilated, and are invaluable for all chronic affections of the leg, sprains, strains, dislocations, sealing after operations, and for all orthopædic and surgical purposes.



ELASTOPLAST forms the base of a number of speciality dressings, complete with pads of medicated gauze and lint. In various sizes, for every need, they are time-savers for the surgeon and are exceptionally comfortable for the patient. There are various dressings for wounds, fingers, eyes, boils, vaccinations, and Capsicum and Belladonna Plasters.

Elastoplast
Ankle or Foot Dressing.

Large Wound Dressing.

Small Wound Dressing.

ELASTOPLAST PRODUCTS ARE RECOMMENDED AND PRESCRIBED BY LEADING SURGEONS AND ARE ALREADY IN CONSTANT USE IN SEVERAL LONDON AND PROVINCIAL HOSPITALS.

London Specialist

——— presents his compliments, and begs to say that he is impressed with the good points about ELASTOPLAST.

K.C.V.O., C.B., M.S.

"Extremely useful, and I am glad you have been successful in producing a plaster both adhesive and ventilated. This removes the cause of troublesome 'plaster rash,' and the patient experiences a degree of comfort unknown with rigid plaster. The wound dressings are a boon in a busy surgery, being so readily adaptable."

——, M.B., Ch.B., R.A.M.C.

Provincial Specialist

It is the only plaster I have ever put on my own skin which has caused no irritation.

M.B., C.M., F.R.C.S.

You are invited to write for free samples and literature direct from the manufacturers, or they may be obtained from your usual surgical supply house.

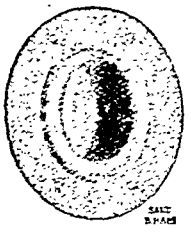
SALTAIR SURGICAL SERVICE



SALTAIR SURGICAL SERVICE

Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

Salt and Son Ltd.

View of Cup showing moulded rubber pad which fits snugly against the body.

Side view of Cup. The Cup flange and circular pad are made as one moulding.

SALT'S COLOSTOMY BELT

WITH STERILIZABLE RUBBER CUP

(REGISTERED No. 749046).

This Belt is specially designed for cases where fæces are of a solid nature or the amount is small.

The special feature is the Cup, which is made of moulded rubber in one piece.

It has no corners or crevices and therefore does not retain the odour.

The advantages in this Belt are:—

1. Detachable Cup sterilizable by boiling, repeatedly without deterioration.
2. No crevices or metal fittings to hold fæces.
3. Smell reduced to a minimum.

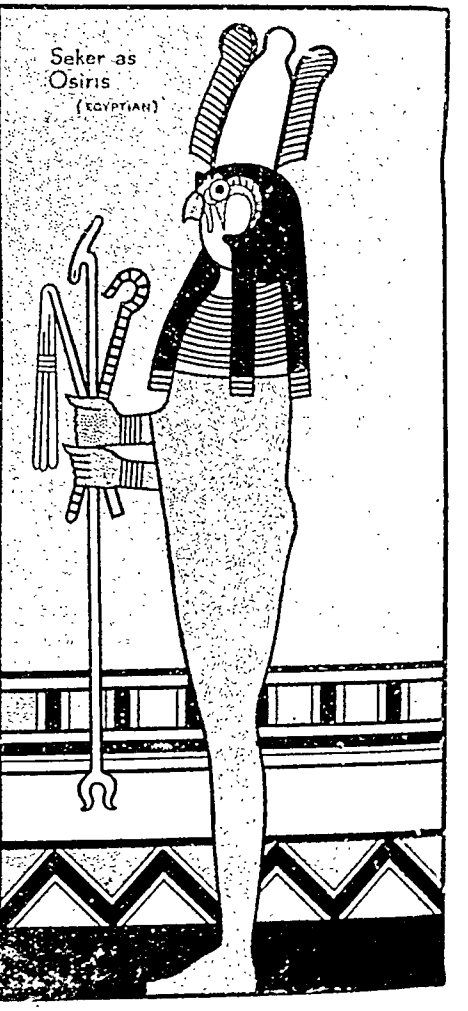
OVALTINE

AN EFFICIENT GALACTAGOGUE.

In addition to its value as a means of promoting the nutritional welfare of the mother and child, clinical experience extending over many years has conclusively shown that "Ovaltine" has specific galactagogue properties. As a result of its administration, there almost invariably follows a marked improvement in the flow and quality of the milk.

The following is an example of many reports received:

"In more than one case I have found 'Ovaltine' bring back the milk supply after everything else had been tried. In one case I discontinued the use of 'Ovaltine' after the desired result had been obtained, but I found at the same time the milk supply also diminished, necessitating the resumption of the use of 'Ovaltine.'"



To ensure adequacy of the milk supply many physicians order the use of "Ovaltine" to commence during the eighth month of gestation and to be continued throughout the nursing period. In this way the mother is not only enabled to withstand the extra strain which the childbirth throws upon the system, but to nurse her child from the outset in the best possible way. "Ovaltine" is delicious as well as highly nutritious, and involves no troublesome preparation.

A liberal supply for clinical treatment sent free on request.

A. WANDER, Ltd., 184, Queen's Gate, S.W. 7.

Works: KING'S LANGLEY, HERTS.

If your patient must stop sugar

It is well known to the Medical Profession that a child's craving for sweets is natural, as a child requires a large supply of an easily assimilated hydrocarbon. Unfortunately ordinary sugar upsets the digestive functions of some children, and "glucose," recommended in its place, is too often of unknown composition and too expensive.

The monosaccharides of fruit-sugar offer obvious advantages over the di-saccharide, sucrose, and a pure and very palatable mixture of dextrose and lævulose is now available under the trade name of SUNNYCOMB.

SUNNYCOMB was first made at the request of some members of the Medical Profession who desired a reasonably cheap monosaccharide for sweetening baby-food for babies who were not flourishing. The results were so satisfactory, and the product so palatable to both young and old, that it was decided to make it generally available.

SUNNYCOMB supplies the necessary carbohydrates in an easily digestible form, being so readily assimilated that it does not upset the digestive functions as ordinary sugar sometimes does, yet it is at the same time a pleasing and appetising delicacy.

SUNNYCOMB is made by Macfie & Sons, Limited, who first started in 1783 and have been sugar refiners in Liverpool continuously since 1837. They guarantee it to be a pure wholesome product and will willingly supply free samples and full information about it to any member of the Medical Profession on receipt of a postcard.

PHEDROS

SYRUP EPHEDRA COMPOUND-MULFORD

PHEDROS is a new cough syrup containing the antispasmodic properties of the Chinese drug Ephedra (Ma Huang), the expectorant properties of Squill and Ipecac, and the stimulant property and salt action of Ammonium Chloride.

PHEDROS is recommended to relieve the paroxysms and allay acute symptoms of coughs, bronchitis, etc.

Each fluid ounce contains:

Chloroform	2 minims
F. E. Ephedra	40 minims
Syrup Squill	180 minims
Syrup Ipecac	40 minims
Ammonium Chloride	8 grains
Syrup Tolu	q.s.

DOSE: One to two teaspoonfuls according to age.

Builds up in underweight conditions and provides a perfectly balanced, highly nutritive diet for growing children

TO the problem of the "underweight" child Horlick's Malted Milk provides a convenient solution.

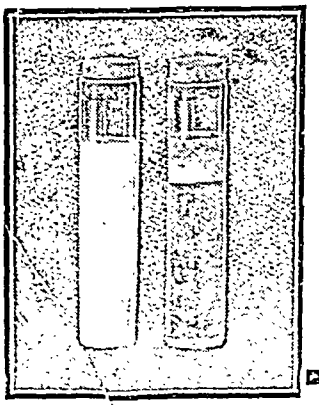
For many years it has been successfully used by the medical and nursing professions for fast-growing children, for invalids, for expectant and nursing mothers — in all cases where it is particularly important to sustain strength and replenish natural energy quickly.

Excellent results obtained by adding Horlick's to the diet of growing children have been strikingly recorded in many thousands of letters written by parents and members of the medical profession.

Made from fresh, full-cream cows' milk, selected wheat and malted barley, Horlick's Malted Milk constitutes a perfectly balanced food — containing fat, proteids, and soluble carbohydrates in correct nutritive ratio.

The vitamins of its constituents are unimpaired by the Horlick process.

Horlick's contains neither cane sugar nor unaltered starch, but presents in proper proportions a sufficiency of valuable malt sugars, for which children have a greater toleration. Moreover, Horlick's is partially pre-digested during manufacture, thereby assuring perfect assimilation.



In addition to its important body-building qualities, Horlick's has the advantage of being an extremely palatable beverage. Most children like the natural flavour of malt and will drink Horlick's with pleasure. And it is now obtainable also in a new Chocolate Flavoured form — identical in constituents with the original Horlick's, but with fine chocolate added.

Horlick's Malted Milk (both forms) is obtainable everywhere in sealed glass bottles, at 2/-, 3/6, 8/6 and 15/-. Also in tablets.

Further details and supplies for tests may be obtained from Horlick's Malted Milk Co., Ltd., Slough, Bucks.

Action of Lysolat compared with that of Carbolic Acid on Pathogenic Organisms

The exceptional germicidal value of Lysolat is due, in great part, to its solubility and stability even in circumstances that destroy other antiseptics. The left-hand test tube below shows Lysolat in a state of perfect emulsification in a 3% solution of Sodium Chloride, whilst a well-known liquid Lysol (right-hand test tube) has broken down under the same conditions.

A number of significant experiments have been made by Prof. Edmund Huynen of the State Veterinary University of Brussels to test the efficacy of Lysolat as a germicide. He used 1% solutions of Lysolat and of Carbolic Acid. It was ascertained that while the Lysolat solution represented a cresol concentration 3.5 times weaker than the carbolic acid solution, it was actually 5 times more powerful.

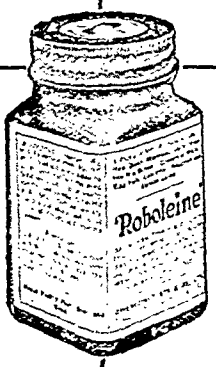
The following are the results of Prof. Huynen's experiments:

(1) Bacilli Pyocyaneus and Coli were destroyed by the Lysolat solution in 8 mins. at 18°, in 5 mins. at 26°, and in 2 mins. at 37°.

(2) Bacilli Bang and Paratyphoid were destroyed by the Lysolat solution in 1 min. at 37°.

(3) Bacillus Staphylococcus was destroyed by the Lysolat solution in 4 mins. at 37°.

In the latter case the carbolic acid solution required a contact of 120 mins. to destroy the Staphylococcus under identical conditions. At 26° the Lysolat solution proved to be 15 times stronger, and at 18° 12 times stronger than the solution of carbolic acid.



Lysolats (LYSOL TABLETS)

PATENT 118667

Lysolats are packed in handy tins containing 40 and 80 tablets (at 1/3 and 2/- respectively), and also in tins of 1,000 tablets.

Members of the Medical Profession are invited to write for free samples of Lysolats to Solidol Chemical Ltd., Ashmead House, Disney St., London, S.E.1

Irritable Bowel

Nujol is of great assistance in the treatment of chronic irritable bowel. Unlike cathartics, whose action is stimulating to the muscles or irritating to the lining of the intestines causing excessive secretion of mucus, Nujol acts merely as a gentle lubricant and solvent of impacted fecal matter. Though it absorbs intestinal toxins to a high degree, it cannot, itself, be absorbed. Consequently, toxemia is prevented, peristalsis is at a natural rate, and the stool is normal and properly formed.

FOR NEARLY A CENTURY
THESE ESSENCES
HAVE BEEN PREFERRED
BY THE MEDICAL PROFESSION

JUST on a hundred years ago Brand & Co. first offered their Meat Essences. From that time until now Brand's Essences have achieved fame because of the exclusive conditions and care under which they are manufactured.

Experiments have proved that Brand's Meat Essences are powerful exciters of the gastric juices. They rouse appetite, and their goodness is rapidly absorbed without strain on the digestive organs.

Brand's Essences are the pure juices of the finest freshly killed chickens, beef and mutton extracted by an exclusive process under hygienic conditions. No preservatives or other substances are added. Brand's Essences (Beef, Chicken and Mutton) are obtainable at chemists and stores throughout the world in small and large-sized tins and jars. Brand & Co. Ltd., Mayfair Works, Vauxhall, London, S.W.8.

Disturbances of Menstruation & the Menopause

The close association between the efficient action of the ovaries and the blood calcium index, provides a good reason for the administration of Kalzana in these cases. The chemical composition of Kalzana, calcium-sodium-lactate, is unique, and the special feature of the sodium element is that it raises the blood alkalinity, thereby promoting the retention of the calcium constituent.

Recent clinical notes state:

"I tried Kalzana on a patient who was suffering from anaemia due to disorder of menstruation (Menorrhagia). I obtained the most excellent results with it. The patient regained her original health and the menstrual period was regulated."

"I have now had three patients on Kalzana, all for menorrhagia, and it has benefited all three. One of the three also had acute dysmenorrhoea; this is cured apparently."

Kalzana is dispensed by Chemists in air-tight packets containing 50 and 100 tablets. Free from harmful by-effects and is pleasantly flavoured.

Kalzana

Made by A. WULFING & CO. (Foreign Produce).

Supplies for your own dispensing, and for Hospitals, Sanatoria, etc., are available at 15/- per 1,000 tablets. Adequate samples for clinical trials, sent with pleasure, upon request.

Local Anæsthesia in Surgical Practice

REMOVAL OF CARBUNCLE.

TYPICAL CASE.

P. C., aged 45 years, physician (object strenuously to taking General Anæsthesia).

Diagnosis: Carbuncle of neck.

Operation: Excision.

Anæsthesia: Infiltration block, using 60 c.c. of 0.5 of 1 per cent. Novocain-Adrenaline solution.

Operation: The infiltrating needle was carried 5 cm. beyond the outer edge of the carbuncle until the latter had been completely isolated from its nerve supply, when it was removed, absolutely without pain to the patient. The base was then cauterized and packed. The wound healed kindly.

—Extract from Practical Local Anæsthesia (Farr).

(Full technique of this and one hundred other operations under Local Anæsthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANÆSTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

PHYSIOLOGICAL TREATMENT OF CONSTIPATION

Total extract of the glands of the intestine Biliary Extract-Agar-Agar-Selected lactic Ferments

TAXOL

LABORATOIRES RÉUNIS LOBICA, 46, Avenue des Ternes, PARIS.

PITUITARY
(Posterior Lobe)
EXTRACT
B. D. H.

Pituitary (Posterior Lobe) Extract B.D.H. produces definite physiological effects:—

Contraction of uterine muscle, raising of blood-pressure, stimulation of peristalsis.

The value of this product, therefore, in obstetrics, in surgical shock and in intestinal stasis is established.

Recent work confirms the opinion that a number of separate active constituents are contained in the pituitary body (*B.M.J.*, Sept. 28, 1929, p. 596). The two main principles are those which are responsible for the oxytocic and pressor effects.

Pituitary (Posterior Lobe) Extract B.D.H. is accurately standardised for these two effects, with the result that the product is guaranteed to be uniformly potent and to possess the maximum physiological activity.

BOOTS PRODUCTS

"VITAMALT"
REGD.

RICH IN ESSENTIAL VITAMINS A, B, C AND D.

The importance of Vitamins and vitamin-containing preparations is being emphasised by an ever-increasing number of the medical profession. It has been accepted that Vitamins A and D in correct proportion and as an extra-dietary measure, are invaluable for the maintenance of good health.

Vitamalt is a scientifically correct well-balanced combination of vitamin-containing constituents and, as such, has achieved much success as a valuable tonic food. Its content of Vitamin A renders it an effective agent for controlling infective processes and makes it in every way a preparation which may be prescribed with confidence when treatment of this type is indicated.

PUERPERAL SEPTICAEMIA

It is now generally recognised, and has been again recently stressed by gynaecologists, that the principal causative agent in Puerperal Septicaemia is the Streptococcus Haemolyticus.

It is an interesting and important fact that Monsol, which is well known to have a selective action on Gram-positive organisms, has a particularly selective action on the strain Haemolyticus among the Streptococci.

The following table showing the relative dilutions at which Monsol is effective illustrates this.

STRAINS OF STREPTOCOCCI

DESIGNATION OF STRAIN	*SOURCE*	*DILUTION OF MONSOL*
"Diphtheritic"	Throat	1-100
Salivarius. Barnes 445	Mouth-Tonsillitis	1-100
Erysipelatis. 226	Lesion	1-150
Enterococcus Tissier 775	Faeces	1-150
Urine 8213	Urine	1-150
Rheumaticus. Beattie	Joint	1-300
Sputum A	Unresolved pneumonia	1-700
Sputum B	Unresolved pneumonia	1-700
Viridans 1080	Tonsil	1-1000
HAEMOLYTICUS 2060	—	*1-1500*
HAEMOLYTICUS B.C. 1498	—	*1-1500*
Mastitidis 2470	Mastitis	1-1500
Scarlatinae. Sherman 1892	Scarlet Fever	1-1500

The use of Monsol in obstetrics is, therefore, specially indicated owing to its selective germicidal power; while its non-irritant action on the most delicate mucous membranes and tissues, renders possible its use at dilutions far stronger than are germicidally necessary.

MONSOL PREPARATIONS INCLUDE:
MONSOL LIQUID, OINTMENT, INTERNAL CAPSULES, PASTILLES, DENTAL CREAM, TOILET SOAP, ETC.

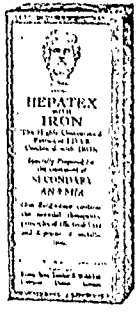
MONSOL BRAND



HEPATEX **WITH IRON**

(Aesculapius)

TREATMENT OF

Severe Secondary Anæmias

For the treatment of the severe secondary anæmias the use of liver in itself is of inconstant value. Likewise the administration of iron, while undoubtedly beneficial, does not always ensure that degree of improvement which is desirable. Liver and iron combined, however, have proved most effective.

HEPATEX WITH IRON provides a rational treatment for severe secondary anæmias. One drachm contains the essential therapeutic principles of 2 ozs. liver and 1 grain of iron. This iron, compared with ordinary iron preparations, is greatly superior as regards assimilation and absence of gastro-intestinal disturbances.

Issued in 2-oz. bottles, 7/6 each.

Brochure on application.

SOLUTION

FOR THE TREATMENT OF

ECZEMA & URTICARIA

Dr. Thos. M. Paul, in "The Urologic and Cutaneous Review," Vol. XXXIII, No. 11, 1929, states in the opening paragraph:—

"To state that hives will disappear in fifteen minutes, that the itching and oozing of an eczema will cease in half an hour, and that an eczematous lesion, regardless of its degree of lichenification, will vanish in a few days, as the result of a hypodermic injection, seems preposterous, yet such has been the writer's experience in a series of sixty-one cases."

We have a few copies of the actual article for loan to interested Dermatologists.

NATURALLY RICH IN VITAMIN "D"

Smiler. fed on Cow & Gate

"Dried Milk for Safety"

At————deaths from diarrhoea and enteritis fell from 105 in 1923 to 67 in 1924, but rose to 109 in 1926. There was a fall in 1927 to 61, and a further fall in 1928 to 56. Professor ————M.O.H., writes: "Once more the relationship between these diseases and the sub-soil (four-foot) temperature, which used to be so constant, failed to re-appear. Among the most important factors in bringing about this amazing decline in mortality from these causes, I think we must place the wide substitution of dried milk for so-called fresh but highly contaminated milk————" Dr.————adds that until the methods of the farmers and others concerned in the milk industry have been revolutionised, and consumers have been provided with facilities for storage and education in the handling of milk, he is definitely of the opinion that liquid milk should be banished from the dietary of infants.

"Medical Officer,"
Jan. 4th, 1930.

This resumé shows clearly the advance made in medical opinion during the last few years. Figures such as these show conclusively that raw cows' milk—"Nature's food for the calf"—is unsafe and unsuitable for the human infant. Discrimination in the choice of a dried milk food is, however, essential.

The makers of Cow & Gate have for over a quarter of a century endeavoured by every means known to science to produce each year a better product, and in the light of this experience they postulate without fear of contradiction that there is a great gulf fixed between ordinary commercial dried milk and that specially prepared for infant feeding.

Controlled Irradiated Products

IN view of the existence of irradiated products of unknown activity, it is of importance to the medical profession to make use, in vitamin therapy, only of products which have been accurately standardized and have been prepared under scientifically-controlled conditions.

The British Drug Houses Ltd. issue their three well-known vitamin products RADIOSTOL, RADIOSTOLEUM and RADIO-MALT as medicinal substances with *definite guaranteed antirachitic potencies.* These products are sold only by qualified chemists and druggists.

RADIOSTOL

RADIOSTOL (Vitamin D). Biologically standardized so that 1 c.c. of the solution exercises the antirachitic effect of three ounces of high-grade cod liver oil.

Radiostol Solution contains 10,000 antirachitic units per c.c.
Radiostol Pellets contain 6,000 antirachitic units per pellet.

RADIOSTOLEUM

RADIOSTOLEUM (Vitamins A and D). Biologically standardized to contain twenty times the anti-infective Vitamin A activity of high-grade cod liver oil.

Radiostoleum contains 10,000 antirachitic units per c.c.
Radiostoleum Capsules contain 4,000 antirachitic units per capsule.

RADIO-MALT

RADIO-MALT (Vitamins A, B_1, B_2, and D). Biologically standardized at a strength to provide prophylactic doses of the four vitamins.

Radio-Malt contains 1,000 antirachitic units per ounce.

PORTIONS OF TWO SABEAN INSCRIPTIONS IN WHICH ARE RECORDED RESPECTIVELY THE BURSTING OF A GREAT DAM AT MA'RIB AND ITS REPAIR.—The extract from an inscription here reproduced on the left tells how there came to the king alarming news from Ma'rib—the dam had burst, as well as the walls, the tanks and the cisterns. That on the right describes the repairing of the several parts and notes the different kinds of stone employed. The monograms enclosed within a cartouche have not definitely been deciphered. Remains of the actual reservoir and canals have been traced among the ruins of Ma'rib. These provide evidence of skilful engineering work carried out by the pre-Islamic pioneers who brought about in Arabia a degree of civilisation higher in some directions than she has ever maintained since. According to tradition it was the bursting of the dam that brought about the decay of pre-Islamic Arab civilisation. This would, however, constitute an anachronism, for the deterioration set in about 115 B.C. and is attributed to the loss of prosperity following upon the establishment by the Ptolomies of an overland route from India to Alexandria, which deprived the Arabs of the carrying trade through their own land. The kingdom was finally destroyed by the Aksumite invaders from Abyssinia in the sixth century.

BELLE VUE SPA

TREFRIW, NORTH WALES.

(Railway Station: Llanrwst and Trefriw.)

COMBINED TREATMENT OF ARTHRITIS

By Chalybeate Waters, Tonic Baths and Extension Appliances

The Belle Vue Spa Hotel provides accommodation for patients for whom these tonic chalybeate waters are indicated. External treatment by tonic baths, as well as by manipulation and extension and light, is also provided.

Recent analyses of the Belle Vue Spa waters show that they are exceptionally rich in ferrous salts. Samples have been repeatedly examined by the Clinical Research Association.

The Association's Report, dated June, 1929, states that the Iron as ferrous sulphate occurs in these samples in proportions varying from 170 to 1,275 grains per gallon, combined with Aluminium Sulphate and free Sulphuric Acid.

Under expert advice the drinking service of the Belle Vue Spa water is now taken from selected sources in the water-yielding rock, and served fresh at the Spa at a standard strength of 2 grains of ferrous sulphate in one ounce.

For patients who are unable to visit Trefriw and take the water on the spot, it is bottled and exported at the same standard strength for medical use in their own homes.

In suitable cases of arthritis and rheumatic disease Hoefftcke's manipulative and ambulatory extension treatment can be applied.

Mobility and freedom from pain in crippling arthritis of the hip and knee can often be obtained, even after shortening and contraction have occurred. This is effected by the extension appliances, which maintain continuous extension by day and by night. The appliance usually permits the patient to walk, and not only supports the weight but replaces the undesirable state of compression of the leg by one of active stretching.

This method secures:—

(1) Extension without muscle loss, inevitable whilst the patient is kept in bed.
(2) Extension without vascular stasis, which occurs when a joint is kept at rest.
(3) MOVEMENT WITHOUT PAIN.

The result has been a restoration of joint function in many cases which had been regarded as hopeless and incurable.

Close co-operation is maintained with the patient's own physician.

Further particulars may be obtained at Belle Vue Spa or 7, Harley Street, W.1.

Hunterian Oration
ON
HERO WORSHIP IN SURGERY.

DELIVERED BEFORE THE ROYAL COLLEGE OF SURGEONS OF ENGLAND ON FEBRUARY 14TH, 1930,

BY

ERNEST W. HEY GROVES, M.S., F.R.C.S.,
PROFESSOR OF SURGERY IN THE UNIVERSITY OF BRISTOL.

"*One comfort is, that Great Men, taken up in any way, are profitable company. We cannot look, however imperfectly, upon a great man, without gaining something by him.*"—CARLYLE, *Hero Worship.*

WE have met to-day on the birthday festival of John Hunter, one of the greatest heroes of English surgery. Considerably more than a century has elapsed since, in 1814, this Oration was founded by Hunter's executors, Dr. Matthew Baillie and Sir Everard Home, "in honour of surgery and in memory of men by whose labours it has been advanced." In pursuance of this bequest the Oration has now been delivered seventy-five times, thirty-eight of which have been in the present theatre. Of these, sixty-eight have been published and are now in our library. It would be presumptuous on the part of the present speaker to utter one word without having first read all these published orations. They now cover a sufficient period of time (1814 to 1928), and that a period of the greatest growth and activity in surgery, to make their perusal one of great interest and instruction, especially in marking notable landmarks in the history of surgery and of this College.

Some Notable Hunterian Orators.

The first Oration was delivered in 1814 by Everard Home. He was Hunter's brother-in-law, and will always be famous as one of the founders of this festival and infamous as the destroyer of the great bulk of Hunter's manuscripts.

William Norris, in 1817, after tracing the beginning of the improvement in modern surgery to the teaching of anatomy, states that "in London there are seven large hospitals." In 1818 Sir David Dundas enlarges on a theme already mentioned by Home in the first Oration—namely, the emancipation of surgery from medicine. He says: "If at any former period surgeons allowed themselves to be under the control of physicians, that is not likely to happen again." In 1819 John Abernethy makes a plea for a legal provision of bodies for dissection. Of Hunter he says: "Those who far precede others must necessarily remain alone." Sir Everard Home, giving the Oration for the second time in 1822, and now raised to the dignity of a baronetcy and the Presidency of this College, refers to the granting of the Charter by George the Fourth, by which this College became "The Royal College of Surgeons."

Sir William Blizzard, in 1823, states the "council of this College are unshaken in their confidence in the efficacy of vaccination." The same orator deplores the practice of surgery by unqualified persons, and also the establishment of special military and ophthalmic hospitals. Samuel Cooper, in 1832, refers to the "noble and opulent as the patrons and dupes of murderous quackery."

Sir Benjamin Brodie, in 1837, speaks of Hunter's work being the first instance of the inductive method of philosophy being applied to pathology. He refers to the completion of the new building. Babington, in 1842, says: "John Hunter's discoveries are great in themselves, but their true value is to be found in numbers of other discoveries to which they have given birth." Arnott, in 1843, discusses Hunter's operation for aneurysm, and refers to 389 cases in which the operation had been done, with 277 successes.

Sir William Lawrence, in 1846, mentions that Paget had been appointed to prepare a catalogue of the pathological specimens in the Museum. He enters into a heated defence of the policy of the Royal College of Surgeons and a criticism of the proposal for a Royal College of General Practitioners. Joseph Henry Green, in 1847, refers to the recent institution of the Fellowship of the College and speaks most eloquently on the value of a liberal education. Richard Grainger, in 1848, speaks of the recent development of the science of embryology.

In 1849 the Oration was for the first time graced by the presence of Royalty. Caesar Hawkins, speaking before Prince Albert about the great progress of the Museum, notes the increasing international co-operation by scientific workers. He refers to the discovery of anaesthesia.

In 1859 John Bishop refers to the work of Virchow and of Lister. In 1861 Coulson mentions that Hunter's remains had been transferred to Westminster Abbey. In 1875 Le Gros Clark refers to the proposed co-operation between the Colleges of Physicians and Surgeons in the conduct of a conjoint examination.

Sir James Paget, in 1877, speaking before the Prince of Wales, says: "In the world of mind, he that is mortal may produce that which becomes immortal." Sir George Murray Humphrey, in 1879, makes the first reference to the antiseptic treatment of wounds; he refers to the practice of ovariotomy by Keith and Spencer Wells. Spencer Wells, in 1883, speaks of the progress of abdominal surgery, the discovery of bacteria, and of Cheyne's visit to Koch's laboratory. Henry Power, in 1889, speaks of the experiments and research of Sir Joseph Lister and of the erection at the College of special rooms for research. Christopher Heath, in 1897, makes the first reference to the agitation by the Members for a share in the government of the College. In 1899 Sir William MacCormac, speaking before the Prince of Wales, says: "Lister has finally crowned the edifice whose corner stone John Hunter laid." Sir Henry Morris, speaking in 1909 before the Prince and Princess of Wales, discussed the conflict of inductive and deductive philosophy in Hunter's work. Edmund Owen, in 1911, tells us that John Hunter was examined by the Court of Examiners in July, 1763, at the age of 40, and received his diploma. He describes Hunter's inoculation with venereal disease and the effect of this in causing his death. Sir Rickman Godlee, in 1913, mentions that the original 13,600 specimens in the Hunter Museum had been increased to 64,766.

The controversial subjects referred to have been: the teaching of anatomy as the foundation of sound surgery; the emancipation of surgery from medicine; the problem of procuring bodies for dissection; the menace of quackery; and the agitation by Members of the College for a share in its government. The chief matters of surgical advance have included: vaccination; scientific physiology and embryology; anaesthesia; bacteria and antiseptics; abdominal surgery and ovariotomy. Notable stages in the advance of the College referred to have been: the granting of the Charter by George IV; completion of the present building; foundation of the Fellowship; formation of the Conjoint Board; moving of John Hunter's remains to Westminster Abbey; and the growth of the Museum from 13,600 specimens, bequeathed by Hunter, to 64,766. Six times the Oration has been delivered before members of the Royal Family, the first time by Caesar Hawkins, before the Prince Consort in 1849, and the last by Sir Berkeley Moynihan in 1927, before the Princess Mary.

Recent Losses.

When I undertook to deliver this Oration I had hoped to say that all the orators subsequent to 1913, its first centenary, were still with us, but now we have to deplore the death of Sir Anthony Bowlby, who gave the Oration in 1919 and was our President from 1920 to 1922. Intimately known and dearly loved by all the Bart's students who came under his kindly supervision, a sound surgeon and a wise teacher, Bowlby, during the time of the great war, reached the zenith of his fame and influence. He served at the front in France during the entire conflict, and he was largely responsible for the organization and equipment of the casualty clearing stations. No one in trouble at home or in the war ever applied to him for help without receiving it in the form of wise counsel and true comradeship.

Three other men notable in this College have also been recently claimed by death. Thelwall Thomas of Liverpool was a Member of the Council from 1921 to 1927. His skill as a surgeon and his kindliness as a friend will always keep him in our memory, but in addition he has bequeathed the generous sum of £5,000 to the College, which the Council has determined to devote to the benefit of the Library. Thomas Horrocks Openshaw, for many years surgeon to the London Hospital, and chiefly known for his pioneer work in orthopaedic surgery, was a member of the Council from 1916 to 1924. He was a safe surgeon and yet always abreast of the times, and his genial personality and splendid fortitude in the tragic death of his brilliant son greatly endeared him to us. Mr. Victor G. Plarr was the librarian of this College from 1897 to 1929. His quiet and unobtrusive personality made him a stranger to many of our Fellows and Members, but he was always working for the good of the College. That by which he will be best remembered is the work he did in writing lives of the Fellows. The publication of these lives under the editorship of Sir D'Arcy Power is now being undertaken, the expenses being defrayed by Thelwall Thomas's bequest.

We have also to deplore the loss of the last known descendant of the Hunter family in the person of Miss Helen Hunter-Baillie, the great-grand-niece of John Hunter, who died in February, 1929, at the age of 86. She had been a regular attendant at these orations, and had presented a valuable collection of letters and family documents to the Library.

Having given this brief tribute to the memory of men by whose labours surgery has been advanced, I would follow the example laid down by most of my predecessors in mentioning outstanding events in the history and progress of the College.

The Royal College of Surgeons: Outstanding Events in its History and Progress.

The agitation by some of the Members of the College for a direct share in its government, the idea of which was first referred to by Sir William Lawrence in 1846 in his heated denunciation of an attempt to make the Royal College of Surgeons into a Royal College of General Practitioners, and which was first actually mentioned by Christopher Heath in 1897, has continued year by year. It may be said now to have entered upon a new phase, insomuch that the annual meeting at which this topic is discussed, which at one time was the scene of angry strife, is now one of amity and good will. This amity has been further increased by Mr. Buckston Browne's generous endowment for the provision of an annual dinner, at which Fellows and Members meet for convivial intercourse. It is not for me to say if and when the Council of this College will directly represent the 18,000 Members as well as the 2,000 Fellows, but I may express a sincere wish that the change, which is in harmony with the modern democratic spirit, may take place soon. The chief thing which is needed to bring it about quickly is convincing evidence that the change is desired by the great body of the Members.

The attainment of the Fellowship has been greatly facilitated for those in the overseas dominions by arranging for the primary examination to be held each year abroad. The first examination held last year in Canada was so successful that it will probably be repeated each year, and a similar arrangement is now being made for Australia and New Zealand.

Mrs. Macloghlin has left £10,000 and the residue of her estate for the purpose of founding and endowing scholarships for medical students in memory of her husband, the late Mr. Edward Macloghlin, M.R.C.S., formerly in practice in Wigan. A sum of approximately £30,000 has been left by the late Sir George Mackenzie in memory of his friend Sir William Mackinnon, Bt., jointly to the two Colleges for the endowment of medical research.

The Honorary Medal, the award of which was instituted in 1802 for liberal acts or distinguished labours conducive to the improvement of the healing art, and which has only twelve times been given, was this year bestowed upon Sir George Makins, in appreciation of his valuable services to the College, more especially in arranging and describing the series of drawings in the Army Medical War Collection.

Scholarships for research have been founded in this College. Lord Beaverbrook's gift of £1,000 was quickly allocated for tissue culture work, and the need for more permanent endowment was evident. The Council has therefore set aside £500 a year for research work, and generous benefactions from Lord Melchett and Sir Louis Baron have placed at our disposal two more similar sums for a like object, so that there will now be expended on vital research a larger sum of money each year than was received by the College as its total income in the days when Hunter received his diploma. One can hardly question that this movement of greater activity for research would have had Hunter's whole-hearted approval. He spent all his income on his museum and his experiments. The museum was bought by the nation and placed in our trusteeship.

We are proud to think that what originally was a unique collection of 13,600 specimens had increased to over 64,000 when Sir Rickman Godlee delivered his Oration in 1913, and now numbers 72,675, due largely to the addition of the military section acquired during the war, the Onodi and the Strangeways collections, illustrating respectively anatomy of the nose and disease of the joints.

But Hunter's spirit of never-tiring adventure in the search for knowledge, although belauded, has not hitherto been adequately followed. We are too apt, perhaps, to be satisfied with what, after all, is only a collection of dead things, and to forget that Hunter's absorbing thought was that of probing the secret and mystery of life. How he would have been thrilled if he could have used a modern microscope, and yet more if under that instrument of precision he could have seen the living cells growing and dividing! It is therefore a happy thought that among the recent objects of research in this College is that of the culture of living tissues.

One of my predecessors, Sir Rickman Godlee, having spent many hours in the Council room of this College, gazing at the famous portrait of Hunter, became convinced that the look of rapt attention and reverie on his face was an indication that he was absorbed in the contemplation of this great question, "What is life?" The story of the portrait, well known to many here, is nevertheless worth repeating. Hunter had promised to sit for his portrait to Sir Joshua Reynolds, but he proved so restless a sitter that that great painter was in despair of ever getting a soul-revealing picture of Hunter's face. He had made an unsatisfactory beginning as his sitter fidgeted and grumbled, but then, owing to some unknown cause, Hunter became absorbed in contemplation as we now see him. The painter, without a moment's hesitation, turned the canvas round, and hastily but faithfully depicted the face at rest, painting it in the space between the legs of the original portrait. I believe that one of the reasons which have led experts to advise against this picture being restored is the fear that restoration might reveal a pair of inverted legs surrounding the leonine face.

We hope that the recent endowment of research and the building of the new laboratories may go a long way towards removing from us the reproach that, whilst we have treasured and added to the *things* which Hunter left us, we have lost sight of the *ideals* for which he was for ever striving.

Another auspicious event has taken place since the last Oration was given. The President of the Royal College of Surgeons has been elevated to a peerage. Only twice have surgeons been made lords. The first instance was that of Lister, who received his peerage when his days of active surgery were over, but when he was President of the Royal Society. In the second instance we are happy in the knowledge that not only is Lord Moynihan President of this College, but also that he is in the heyday of his surgical virility. Never has his brain been more active, his tongue more eloquent, his hand more firm, or his eye more keen. Because that eye is now upon me I must desist from any further words of eulogy, and I excuse those I have already uttered because it is of this College and the honour which he has brought to it that it is my duty to speak. In Hunter's day surgery was only just emerging from the lowly position of serfdom to medicine. The very name of barber-surgeon indicated this status, half tradesman and half apothecary, and now, two centuries later, the Royal College of Surgeons is presided over by a peer.

Thus far my path has lain on conventional lines laid down by my honoured predecessors, and I felt that I could not venture further without seeking for advice and guidance. For these I have sought for inspiration to speak my best about the great Scotsman, John Hunter, from two other Scotsmen, both of whom, like Hunter himself, came to this city to enlighten our darkness. I asked Sir Arthur Keith, and his answer was "Bones," and I asked Carlyle, and he said "Heroes." In all diffidence, therefore, I will try to follow both their counsels, only asking you to aid my poor words with your imagination in thinking of Keith speaking to you about bones, or of Carlyle thrilling you with his rugged eloquence as he discoursed to you about "the hero as a surgeon."

Hunter's Experiments with Bones.

A great part of Hunter's life was spent in handling bones. Anything big and strong and lasting had as much fascination for him as anything that was curious or

inexplicable. His greedy longing for the skeleton of the Irish giant, satisfied at last by its nefarious purchase, is the best-known instance of this. Hundreds of skeletons of reptiles, fishes, birds, and mammals were prepared, articulated, and preserved by him, and hundreds more were collected as fossils. Indeed, I suppose it would not be far from the truth to say that never before or since has any one man handled so many bones as Hunter. But while his hands were busy with the bones his mind was busy with the questions of their formation and their growth. It is with his specimens dealing with these questions that we must occupy ourselves chiefly to-day. They fall into three categories—the first dealing with growth, the second with inflammation, and the third with transplantation.

In Hunter's day bone was supposed to grow by a process of interstitial accretion. This was the doctrine of Duhamel. True to his principle of "Don't think, but try," Hunter determined to put this idea of bone-growth to the test. He buried two shot, two inches apart, in the tibia of young animals (both the pig and the fowl were used). After a certain period, when the animals had grown considerably, they were killed, and the shot were found to be the same distance from one another but much further from the two ends of the bone, thus proving that the growth in length of a bone was due to additions to its extremities.

Again, knowing of Belchier's discovery, that madder taken in the food is deposited in the bones, he fed young pigs upon food to which madder had been added. By giving and withholding the dye for varying periods and then killing the animals it was proved that madder-stained layers of bone were superimposed on unstained layers, and that as new layers of bone were added to its surface the inner layer next to the marrow cavity was absorbed. He thus proved that the growth of a bone in thickness was due to the addition of new layers of bone to its outer surface, and he recognized the occurrence of the physiological absorption of bone. He went further in this last observation, because he studied it in detail as it occurs in the shedding of a stag's antlers. He even anticipated some of the modern doctrines of internal secretions by noting the effect of castration in stunting the growths of the antlers. In regard to one of Hunter's specimens, the head of a deer, in which the left antler is dwarfed, he tells us that from this animal the left testis had been removed.

In the second group of experiments Hunter demonstrated the process of inflammation, necrosis, sequestration, and the formation of an involucrum in a manner so perfect that his series of specimens stands to-day unique among our pathological collection. No better instance, I think, exists of how badly his tongue and his pen served his hand and his brain than is afforded by the laboured and involved description of the inflammation and necrosis of bones contained in Volume I, Chapter 18, of his collected works edited by Palmer, as compared with the simple eloquence afforded by the specimens from which his learning was drawn. Most of these specimens were obtained by applying the actual cautery to one or other bones of an ass. Possibly this was the same animal the tendo Achillis of which was divided and its union studied, and on which other more elaborate experiments were performed. If this was the case then Hunter's ass certainly deserves a place in history even more honourable than that of Balaam.

In the third group of experiments Hunter showed how animal tissues could be removed from their natural situation and grafted elsewhere. In the most striking of these he cut off the spur of a cock and implanted it into the vascular comb. The transplanted spur not only lived in its new environment, but grew prodigiously. An even more startling experiment was that of implanting a human tooth into a cock's comb, and noting that, having taken to its new bed, it became vascularized, so that an injection into the vessels of the cock passed into the tissues of the transplanted tooth. He transplanted the spur of a hen into the leg of a cock, and obtained perfect healing with good growth of the transplanted bone. This, I believe, is the first instance of successful bone-grafting of which we have any record.

In Hunter's day it was not possible to carry out any but the most simple experiments with bones, because any deliberate exposure and cutting of bone was followed by septic inflammation. Since the advent of aseptic surgery, however, the bones have proved amenable to experimental work as well as to surgical operations.

Macewen's Work.

There have been added to the Museum two notable series of experimental specimens, the one by Sir William Macewen and the other by the Jacksonian Essayist of 1913. The one series is of great scientific and historical interest, because it really settled what may be called the battle of the periosteum once and for all. Until Macewen's work the periosteum was regarded as the veritable matrix of the bone, chiefly because of the work of Ollier of Lyons. But Macewen showed that bone could grow and live without periosteum, and that the so-called periosteal new bone was merely bone which had grown into the periosteum from its basal attachment, and that the periosteum was merely an inert limiting membrane. These ideas were at first scouted by American and Continental workers, but that they have now been converted is proved by the words of Leriche, Ollier's most brilliant pupil: "An area of ready ossification, the periosteum is not a specific organ of osteogenesis"; and "the functional characteristic of periosteum appears to reside in the limitation of ossification."

Quite recently Cowan, an American worker, has shown that not only does the periosteum not produce new bone, but that it is one of the chief agents in preventing the union of fractures, by its capacity of forming dense fibrous tissue, which is apt to grow between the fragments and so hinder the union of the callus which these produce. But the ultimate mystic problem of how bone is laid down and again taken up is not only still far from solution but seems now to us much more complex than it was in Hunter's day. We know a little of some of the distant forces which determine how much bone shall be laid down or to what size or to what density it shall grow.

We know that the ductless glands—the pituitary, the thyroid, the parathyroid, the ovaries—have some influence on the growth of the skeleton; that food elements which can neither be isolated nor analysed—the vitamins—may determine its density; and, most mysterious of all, that not only can sunlight cause bone to grow, but that this sun power can be first given to the food and by this transferred to the bones. In fact, the whole bewildering chapter in physiology called calcium metabolism appears to concern itself with all aspects of life and growth. But even the simple facts of the relationship between bone salts and bone cells are still matters of doubt and dispute. That animal tissues can be grafted was proved by Hunter, but the exact changes which take place in this process are most difficult to understand or explain. Hunter took it for granted when he transplanted a human tooth into a cock's comb and it remained in organic connexion, allowing injection from the bird's vessels to permeate its tissues, that the tooth had become a living part of the cock's tissues. The modern view, however, would be that the vascularization was only that of granulation tissue, by which the foreign tooth would have been eaten away and destroyed.

As I have said before, no practical advantages could have followed in Hunter's time from his grafting experiments. But in the modern era of aseptic surgery bone-grafting has become an everyday method of repairing fractures and of making good defects in the bones. For a time, it is true, the possibility of suture and fixation of bones by metallic substances—wire, plates, screws, and the like—absorbed the attention of surgeons. But both clinical experience and experimental work soon showed the drawbacks and limitations of the use of metal substances and proved the great possibilities of grafting with bone tissue.

The Jacksonian specimens illustrate many of these points, of which the following may be mentioned as the most important. Any metal substance, whether wire or screw, exerting firm pressure upon living bone, causes either necrosis or else absorption of the bone, and therefore is to be regarded as essentially a hindrance to bone growth or repair. This bone destruction, whether by necrosis or absorption, is a vital and not a septic process, but it leads to conditions very favourable to the latter. When, however, metallic fixation is efficient and bone

union occurs, there is produced in the end a reactive inflammation by which the foreign body becomes encased in a layer of dense new bone. Thus the method used clinically may, and often does, lead to painful osteitis, which finally requires the removal of the offending metal.

Living and Dead Bone Grafts.

In regard to bone-grafting, the specimens under consideration give by no means a complete picture of the process. But they do illustrate two points of cardinal importance. The survival and functional union of the graft to the host bone depends essentially upon perfect contact and adequate fixation between the graft and the host. No living graft, however carefully cut even from the same animal, will survive or function if it is laid loosely into the tissues of the host. In other words, the graft manifests no innate vitality of its own. Further, if two small grafts, one of living autogenous bone, the other of dead boiled bone, be fixed firmly in the shape of pegs into holes bored in the living host bone, then at the end of six weeks both will have grown in place and neither naked-eye nor microscopical examination can detect any difference. Dense bone, when transplanted, always dies, in the sense that its cell spaces and vascular channels become empty. It is then invaded by new vessels and inhabited by new bone cells provided by the tissues of the host. From this it follows that in many cases it is just as good to use dead bone in the first place and to trust to the activity of the host's tissues to vascularize and vivify it. Of this I shall show you a convincing proof presently. But it would be going too far to assert that the living autogenous graft has no advantage over the dead one. Certainly when a gap in a bone has to be bridged, the living graft becomes a vital and growing part of the skeleton much more surely and more quickly than does a dead graft. Therefore in such cases as making good the gap left by the destruction of the whole diaphysis by osteomyelitis, or the fixation of a tuberculous spine by the insertion of a tibial graft—a suggestion which we owe to the genius of an American colleague, Dr. Albee—it is better to use the living bone taken from the patient himself. Whether this superiority of the live graft is due to the survival of superficial cells or to its more ready permeability by the host blood vessels we do not know, but it is certainly not due to the survival of the graft as a living entity.

In the beautiful specimen lately presented to the Museum of a double bone-graft of the spine, obtained three months after the grafting operation, the grafts are seen to be in close vital union with the vertebrae. But it is evident that the great vascularity of the grafts represents a new process of permeation and invasion by new blood vessels, as the tibial crests from which they were taken contain no such blood channels.

Probably I have raised in the minds of many of my hearers a feeling of scepticism about the possibilities of dead bones being capable of functioning as real vital grafts—vital, that is to say, in the sense that they become an integral part of the living skeleton. Therefore I will venture to give you three illustrations, which I am happy to say are not dead specimens in bottles, but living, healthy people.

The first is from a lady of 39, who had an ununited fracture of the neck of the femur of two years' duration. The bone was mended by exposing the hip-joint and nailing the head of the bone to the neck after the former had been dislocated. For this purpose a nail, 3 in. long and 3/8 in. thick, made of dead bone cut from a stag's antler, was used. She made a rapid and complete recovery, and to-day, three years after the operation, it is impossible to detect from her active movements which of her hips has been injured. The *x* rays show very well how the bone nail first merely held the broken neck of the femur together, then slowly but surely became incorporated into the living skeleton.

The second instance is in a man of 25, who at the time of the operation was 18. He had developed fibrocystic disease in the upper part of the left femur, which had become reduced to a mere shell of bone, causing a definite aching pain, premonitory of a spontaneous fracture. The exact nature of the condition was revealed by a preliminary operation in which a mass of firm fibrous tissue was found occupying the whole cavity, shown by the *x* rays. An exact model of this cavity was prepared from a tooth of a walrus, which by its curve and size seemed just made for the purpose. The whole cavity in the bone was exposed by cutting a trapdoor from the back of the femur, the fibrous mass was removed in one piece, and the ivory graft inserted. There it remains to this day, surrounded but not replaced by the human bone, the dense ivory having proved resistant to penetration by new blood vessels. The patient, a quarryman, has been in good health and active work ever since. It is to me a happy thought that whilst Hunter was able to graft a tooth into a cock's comb 150 years ago, we have succeeded in implanting a walrus tooth into a man's leg in such a way as to form an integral part of his skeleton.

The third instance is perhaps the most instructive of all, because the dead graft was made to bridge a gap, and has been associated with very active growth of a long bone. The boy, as he then was, ten years ago, between the ages of 7 and 10 had broken the right humerus four times, usually by trivial causes. The *x* rays showed a cyst in the middle of the shaft of the bone. The whole thickness of the affected portion of the bone was cut out for a length of three inches by a subperiosteal resection. The gap was made good by thrusting a long piece of beef bone into each fragment and then bolting together the projecting ends of the grafts. Each graft had had many small drill holes made into it in order to facilitate its penetration by living tissues. He made a smooth recovery without the use of any splint, and was able to return to the dangerous environment of public school life six weeks later. The *x*-ray pictures show how the beef bone has remained in place for ten years, becoming gradually merged, especially at the ends, in the structure of the human bone. That this bone has suffered no diminution of growth from its invasion by an ox bone is evident from the pictures, but that you may be finally convinced of this I have brought the gentleman himself to show you, and you will admit that the addition of a piece of beef bone to his anatomy has not interfered with his growth. (He is now 6 ft. 2 in., and an undergraduate.)

I have selected the study which Hunter made of bones and some of the things which have arisen from it as an example of his work, chiefly because it has not been touched upon by any of my predecessors, and also because it is most familiar to myself, and this leads me to my first observation about Hunter as a great man. Think of it! Seventy-five orations about one man and his work, and still there is left a great subject almost untouched.

Hunter as a Worker.

The first, but I will not say the greatest, claim which Hunter makes to be regarded as a veritable giant among men is his capacity and enthusiasm for work. He came as a young man from Scotland and began his life in London, making anatomical preparations in the school of his elder brother, William; he then taught anatomy and got himself qualified after working at Chelsea, St. Bartholomew's, and St. George's Hospitals. He was already deeply engaged in scientific research work, chiefly in dissecting all the animals he could get. His health threatening to break down, he applied for and obtained a military surgeon's post and served for three years in Belle Isle and on the Peninsula.

On his return to London, his practice having vanished, he began strenuous work in dissecting, describing, and collecting specimens, which was the beginning of the present Museum. He became a surgeon to St. George's Hospital, and he lectured on anatomy and surgery. He acquired a great and prosperous practice, and with its proceeds bought a country place at Earl's Court, in which he collected a veritable menagerie of wild animals and continued with his experiments. He became the Deputy Surgeon-General of the Army Medical Service. He had been for a long time a Fellow of the Royal Society and was already engaged in writing and contributing scientific papers for that learned body. Before he reached the zenith of his fame he had begun to suffer from attacks of angina pectoris, all the symptoms of which he relates with vivid exactitude.

His whole day being taken up with his practice and his teaching and his body racked with an ever-progressive disease, his last thought was of seeking rest or repose. On the contrary, his passion for work kept him up until midnight writing, and awakened him again at four in the morning, when he settled down to his dissecting. If a

stranger wrote to him, wishing to see his work and proffering an introduction from another distinguished surgeon or scientist, Hunter would name 5 a.m. as a suitable hour for an appointment. This all sounds incredible, but its truth is vouched for by many witnesses, including Hunter's arch-enemy, the notorious Jesse Foot.

But in addition to witnesses from the past we have the convincing evidence afforded by 13,600 specimens in the Museum. It is not easy to grasp in a moment the significance of these figures. Hunter began his work at the age of 20 and died at 65. Allowing, then, full forty-five years, and 300 working days in each, we have the total of 13,500 days with 13,600 specimens collected, or an average of one specimen for every day of his life. Many of these necessitated experiment or elaborate dissection, and he also left many folios of drawings, notes, and descriptions, besides those destroyed by Home and the fifty-five papers or treatises written by Hunter or prepared from his notes after his death.

A few people there may be, but very few, who in intellectual pursuits really do work hard, but how many of these continue their self-imposed slavery right up to the end of their lives, even when fame and fortune have smiled upon them? Hunter knew full well that he was suffering from a mortal disease, for he told a friend that his life was at the mercy of any rascal who chose to anger him, and yet he went on at full pressure to the day of his death, when his own prediction came true, and some colleague giving him the lie in the board room of St. George's Hospital he felt that the fatal blow had been struck, and expired in the arms of Dr. Robertson.

Hunter as a Seeker.

This brings me to the next point, which unhesitatingly may be said to be his chief claim to greatness—and this is the driving force which lay behind his work. Hunter was desperately in earnest. He was inspired by a vision of the mystery of life, which called him on and ever onwards, trying, experimenting, asking and seeking to know something of the truth of life and nature. "No man adequate to do anything, but is first of all in right earnest about it; what I call a sincere man. I should say sincerity, a deep, great, genuine sincerity, is the first characteristic of all men in any way heroic." That sentence of Carlyle's I take as literally applicable to our hero.

Nothing serves better to illustrate Hunter's desperate enthusiasm for research than his own deliberate inoculation of himself with disease. Unhappily this experiment was only too successful, though he himself failed to understand, what has been so amply demonstrated by others, that this disease, when it had apparently disappeared, laid relentless hold upon his blood vessels and led to angina and to his tragic death.

It has been many times claimed that Hunter's secret lay in his having adopted the Baconian or inductive philosophy. But others have justly remarked that he often allowed himself to lapse back into the deductive method, and that whenever he did this he wandered from the path of truth. It is highly improbable that he ever consciously adopted any philosophic system. He just went straight to Nature, and, demanding to know the answer to her riddles, he thought nothing of giving his fortune and his life as a price for his knowledge.

In biological science Hunter was the greatest seeker the world has ever known, though by no means the greatest finder. It was his desperate earnestness in seeking, and not merely the products of his research, which then and now rivets men's attention. It was an arresting spectacle to see a Scotsman spending £70,000 in collecting specimens which had no intrinsic value. It was his supernatural faith that there was in Nature something worth seeking which made other men follow his lead. The mere sight of a man earnestly gazing at some object in the street is enough to draw a crowd, who will endeavour to find out what all are looking for. The pioneer who refuses to be satisfied with the bare tillage of the surface soil, worn poor by many generations of cultivators, and, convinced that a rich vein of gold is to be had for the digging, spends all his energies, his fortune, and his life in delving into the earth for buried treasure—who brings up many strange things, which at first only a few know to be auriferous ore—this is the man whose faith and enthusiasm compel others to follow. The pioneer does not himself, maybe, find the largest nugget or the purest gold, but he shows where gold may be found and how to find it.

Such a pioneer was Hunter, and to Lister coming after him was accorded the good fortune to bring to light the most precious treasure that the surgeon-digger has ever given to his fellow men. It was John Hunter's faith and vision which raised surgery from the level of a craft and art to that of a science, and which has proved an inspiration to his followers. "For consider," as Carlyle says, "what mere time will do in such cases; how if a man was great when living, he becomes tenfold greater when dead."

His Human Frailties.

The wonderful influence which Hunter exerted upon contemporary thought is made much more remarkable when we consider his many shortcomings and frailties. He was gifted with neither learning nor eloquence. Of his writings I am almost tempted to quote what Carlyle says of Mahomet's Koran: "I must say it is as toilsome reading as I ever undertook. A wearisome, confused jumble, crude, incondite; endless iteration, long-windedness, entanglement." I sometimes wonder whether his brother-in-law, who afterwards became Sir Everard Home, the first President of the Royal College of Surgeons, deserves all the obloquy which has been heaped upon him for taking a cartload of Hunter's unpublished writings away with him and quietly destroying them, after he had extracted so much learning from them as, by papers contributed by himself to the Royal Society, earned him a Fellowship in that body.

Although Hunter lectured for many years he found it a painful task, and often took laudanum beforehand to quiet his discomfiture. He had none of the classic learning considered essential for a scholar in his day, and even when he had a chance of acquiring it at Oxford he impatiently threw it aside, saying that he would rather learn from living Nature than from dead languages. Even in these uncouth days Hunter was a rough customer. He was always quarrelling—whether with fellow officers in his military service or with his own brother, or other workers at home. He bursts into his wife's drawing room and addresses her visitors: "I knew nothing of this kick-up: I ought to have been informed of it beforehand, but as I am now returned h me to study I hope the present company will retire." It seemed that he must quarrel even to the end, even though it cost him his life.

If it should seem strange to mention these human frailties when speaking of one who was truly a hero, if ever there was one, I do it deliberately in order to emphasize that Hunter owed his influence to the greatness of his work, the almost blinding sincerity of his vision, and to his unquenchable enthusiasm, rather than to any charm of manner or polish of language. I must quote Carlyle again when he says: "On the whole we make too much of faults; the details of the business hide the centre of it. Faults? The greatest of faults, I should say, is to be conscious of none."

His Heritage and Inspiration.

To the whole surgical world who have come after him Hunter's most priceless bequests have been his inspiration and his heritage. The heritage is here as the most wonderful museum of its kind in the world; the inspiration is impossible to limit or define.

We know that Hunter's experimental methods laid the foundations of modern physiology and pathology. He taught us to seek out the relations between structure and function in the normal tissues and between disorder and disease in the morbid. In his collection of animals and of fossils and his observations on development, with its parallelism between the growth of the individual and the elaboration of the race, he came very near to the Darwinian theory of evolution. His methods, closely followed by Lister, were the basis of the discovery of the antiseptic treatment of wounds. "Worship of a hero is transcendent admiration of a great man." The great turbulent heroic soul of Hunter has never lacked this worship, or else these seventy-six orations have been poor sham mockeries.

But even if we admit that orations are but empty words, there exists a far more vital evidence that the torch of inspired enthusiasm has been faithfully handed down from his day until now.

First, there was that dear old man Clift, who like a watch-dog guarded his master's treasures after his death, when it seemed that nobody wanted them. For seven years he lived on seven shillings a week, whilst he kept his trust, and then later became the first formal custodian of the Museum. The watch-dog growled and showed his teeth, but, alas! could do no more when his master's precious papers, many of which Clift had himself helped to write, were carted away and secretly destroyed by Home. Clift's daughter married Richard Owen, who succeeded him in the guardianship of the Hunter Museum and became the greatest palaeontologist and comparative anatomist of his day. He was later transferred to the Natural History Museum at South Kensington. Owen was followed by Paget, a most notable torchbearer, whose ceaseless labours added so much to surgical pathology, and whose silver-tongued eloquence is remembered by many now living. Then came the greatest of Hunter's followers, Lister, whose name is held in honour all the world over as the one whose work has saved more lives and suffering than have been sacrificed by war. Lister, it is true, never held high office in this College, though he was a member of Council for eight years. His gentle soul did not love fighting with his detractors, and he preferred to pursue his quiet research in the laboratory and at the bedside. And lastly, we are fortunate in having to-day, in the person of our beloved Curator, Sir Arthur Keith, one on whom the mantle of John Hunter seems perfectly to rest, the depth of whose learning and the eloquence of whose tongue fit him so well to be the guardian of Hunter's heritage and the exponent of Hunter's inspiration.

Hunter may truly be said to have raised the idea of the scientific pursuit of truth to the level of that compelling influence in men's lives which is called religion. For he had a vivid faith in his quest, an unquenchable enthusiasm for his ideal; he left an inspiration for all who come after him, and a real hero for us to worship.

ADVANTAGES TO THE DIABETIC OF A DIET RICH IN CARBOHYDRATES.*

BY

J. A. NIXON, C.M.G., M.D., F.R.C.P.,

PROFESSOR OF MEDICINE IN THE UNIVERSITY OF BRISTOL; PHYSICIAN TO BRISTOL ROYAL INFIRMARY.

WHEN Banting revolutionized the treatment of diabetes by the introduction of insulin he provided a means whereby the diabetic can metabolize carbohydrate. It was unfortunate that this discovery should have come at a time when Allen had revived Guelpa's method of treating diabetes by starvation. Because the "starvation" method unquestionably became grafted on to the insulin method of treatment, with the result that, in addition to the necessary evil of having to endure daily hypodermic injections, the diabetic is often subject to deliberate and, in my opinion, unnecessary degrees of undernutrition. The high fat dietary is another survival from pre-insulin days.

The practice of feeding diabetics with an excess of protein was more readily dropped when insulin was introduced, although many advertised diabetic foods still claim as a merit their high protein content. I cannot conceive that in these days there is any advantage to the patient in offering as a substitute for carbohydrate an excess of fat or of protein. For, to speak plainly, if a diabetic deprived of carbohydrate does not convert the fat or protein of his food into glucose or glycogen he dies. There are a few people so constituted that they can derive from fats and protein an adequate glycogen supply—the Eskimos as a race seem capable of this physiological *tour de force*. In our race or our climate the healthiest of us mostly fail miserably if we try to accomplish it. The diabetic, with or without insulin, is equally liable to fail; it is almost a miracle when he succeeds.

The question I propose to consider is whether a diabetic need nowadays ever be asked to attempt either the task of deriving his glucose exclusively from fats and proteins or the alternative task of living cheerfully and working usefully whilst balancing on a sort of knife-edge of starvation.

The importance of keeping the blood sugar low if a diseased pancreas is to have a chance of recovery is universally admitted, but the prospects of recovery are decreased if the low blood sugar is accompanied by a general starration. A starved pancreas will not regenerate, even though the blood sugar is low; new tissues are not built up by such means.

Before, however, the regeneration of the pancreas is considered, there may come the far more pressing question of keeping the diabetic patient alive. The first fear is that diabetic coma may supervene. Insulin treatment has reduced the mortality from coma to such an extent that one can say "a death from diabetic coma is not an unnecessary death." Nevertheless diabetic coma is not an unreal danger even to-day, and it is only by constant supervision on the part of the doctor and intelligent co-operation on the patient's part that this danger is averted.

We know that the chief factor in the production of diabetic coma is incomplete oxidation of fats. These fats may be either exogenous, the fats of food, or endogenous, the fats of the body. If insufficient carbohydrate is ingested, the body endeavours to derive its calorie wants from the fats; in any case a certain amount of carbohydrate is required to secure complete oxidation of the fats. If the oxidation is incomplete ketosis ensues, and finally such a degree of ketosis is reached as produces coma and death. Thus if a patient with diabetes, in whose urine acetone bodies are present, comes under observation the immediate aim of treatment is not to regenerate the pancreas, it is to prevent coma. The treatment of coma when established is admitted to be the administration of glucose rendered usable by insulin. No one urges that the least particle of fat is needed when the patient is comatose.

When treating a diabetic I am never satisfied so long as any trace of ketone bodies can be detected in the urine. I know that Rothera's sodium nitro-prusside test is unduly delicate, but it seems to me that any patient who has had sufficient ketosis to give a positive ferric chloride (Gerhardt's) response, may as well be cleared completely, even to the point where Rothera's test becomes negative. In like manner, when Rothera's test becomes positive in a diabetic where previously it was negative, it is better to push the patient back on the safe side and render the urine completely negative, rather than let him continue on a path, whose width we cannot presume upon, which divides a positive Rothera's reaction from a negative Gerhardt's.

In a patient showing even slight ketosis there seems no sound reason for administering fats at all. The first object is to eliminate the ketones, and we only know one practical way of doing this—namely, the administration of carbohydrate. When the subject of ketosis is not a diabetic we give glucose, either by the mouth or intravenously, but if diabetes is present then insulin must be added to enable the ketones to be oxidized with the carbohydrate. If the diabetic patient should chance to have a high blood sugar it may be that insulin alone will enable the blood sugar to be utilized, but there is no way of determining whether the blood sugar all by itself is sufficient to counteract the ketosis when insulin has been given.

One may meet with a patient in diabetic coma with hypoglycaemia, because the insulin has enabled the blood sugar to be exhausted and yet was insufficient in amount to burn up all the ketones. Obviously this can only be avoided by giving carbohydrates freely with the insulin and ignoring glycosuria. As the majority of patients threatened with coma are under-nourished, we need not fear that their weight will increase immediately. Make them safe first, then consider their nutrition.

The patient with ketosis, however slight, does not stand in immediate need of fat. On the contrary, a diet rich in fat but poor in carbohydrates produces fat deposit rather than glycogen in the liver, and where fat has got in there

* Presidential address to the Bath and Bristol Branch of the British Medical Association, 1929

is apparently no room for glycogen. Now a respectable glycogen deposit in the liver provides to the diabetic who is having insulin a definite safeguard against hypoglycaemia.

A diet poor in fat and rich in carbohydrates is the only way to ensure glycogen storage. So I advocate the withholding of fats for a time in patients with any degree of ketosis, and being generous with the carbohydrate. I give the patient an adequate maintenance diet, replacing the fats as far as possible with their equivalent of carbohydrate—that is, 1 ounce of fat replaced by 2¼ of carbohydrate. I recently had a small boy sent into Bristol Royal Infirmary verging on coma. I ordered my house-physician to give him all the sugar he could eat, and sufficient insulin to restore him to consciousness without bothering about the glycosuria. Also a baby of 18 months was treated with insulin whilst kept on a milk diet, with no added fat.

Diabetic children can rarely do without a generous ration of carbohydrate. Even the normal child is easily upset by a surplus of fat over carbohydrate, which accounts for a certain number of cases of cyclical vomiting, acetonaemia, or acidosis in children. No child should be compelled to eat more fat than he has the taste for. Avitaminosis is not a real danger. Vienna experience showed how little fat added to the diet would avert xerosis of cornea, rickets, etc.

There is another class of diabetic in whom a fat-free or fat-poor diet is an advantage—that is, the patient who requires a surgical operation or an anaesthetic. No surgeon or anaesthetist likes to embark on an operation upon a patient who has not a reasonable store of glycogen. Funk said: "Let us not forget that sugar (glycogen) is the food, and the only food, upon which muscle can live. Especially to be remembered as regards the heart." Fats are no help in the preparation of any patient for operation, less still do they help the diabetic.

Diabetic atheroma is another condition in which a good carbohydrate supply is definitely beneficial and a fat-rich diet is harmful. Joslin remarks that every dose of insulin defers arterio-sclerosis and postpones old age; for it has been observed that the diabetic who develops arterio-sclerosis at an abnormally early age is the severe diabetic kept alive upon a low carbohydrate, high fat diet.

There is another point to be considered in reference to arterio-sclerosis: insulin has been administered in order to relieve arterial spasm, and has proved beneficial in some cases of Raynaud's disease and gangrene; but it has been observed that insulin-hypoglycaemia may actually precipitate an attack of angina pectoris in a patient with a diseased heart. The sclerotic heart, as van den Bergh remarked, may even demand a high blood sugar level.

Pregnancy in the diabetic woman is another state which surely calls for great caution in the administration of protein and fat; I know no solid objection to allowing her all the carbohydrate she asks for. There is a grave doubt whether a high cholesterol content in the blood, such as excessive fats produce, may not damage the kidneys as well as prevent glycogen storage in the liver—a combination of evils which is especially dangerous in pregnancy.

Sansum has been advocating for some time a more generous use of carbohydrate, and Joslin's only criticism is that it may lead to undue gain of weight. Nearly every writer on diabetes advises that the diabetic shall be kept at a weight 10 per cent. below the average for his age and build. I believe the best weight is that at which a person feels fittest and is most active in mind and body.

I always feel sorry for the diabetic who has to take his necessary calories in the more condensed form, say, of butter and cream, and stay the pangs of hunger with cellulose and similar indigestible roughage. Which of us, if given our choice, would not prefer 1 oz. of bread to ½ lb. of cabbage *plus* 5 oz. of brussels sprouts and 5 oz. of lettuce? Our patients are advised to eat Ryvita; four pieces of Ryvita contain more carbohydrates than 1 oz. of white bread. Porridge is not everybody's meat, yet a plate of porridge made with 3/4 oz. raw oatmeal contains the same carbohydrates (15) and protein (3) as 1 oz. of white bread, and 3 grams of fat in addition.

Most children like milk, and it is not so fearfully dangerous; 1 pint contains 30 grams of carbohydrate, 20 of protein, 20 of fat, and in a palatable digestible form. Three ounces of potatoes contain only 20 grams of carbohydrate.

Bear in mind that for every ounce of fat that is omitted 2¼ oz. of carbohydrate may be substituted. So that if we are content with 1/4 oz. of butter instead of the 1 oz. allowed in the Bristol Royal Infirmary basal metabolic diet of 1,679 calories, our meal may contain at least 1/2 oz. more white bread. My experience is that if fats are limited and sugar is omitted few patients will voluntarily exceed a 3,000 calorie diet which contains ordinary carbohydrate and meat. They must, of course, be careful not to take sugar or jam in any form, raw or cooked. That means giving up marmalade for breakfast, sweets for dinner, and jam for tea.

The advantages that may be claimed for allowing diabetic patients a diet rich in carbohydrates appear to be:

Contentment and satisfaction are secured.
The regimen is more readily observed.
The danger of ketosis is removed.
Arterio-sclerosis is delayed.
Most important of all, a fat-poor diet increases carbohydrate tolerance and the prospects of pancreatic regeneration.

MISSED DIAGNOSES.*

BY

JULIUS BURNFORD,

PHYSICIAN TO THE WEST LONDON HOSPITAL, THE LONDON JEWISH HOSPITAL, AND ST. MARY ABBOTS HOSPITAL, KENSINGTON.

KNOWLEDGE of pathological processes and their manifestations grows steadily, and with it has developed a finer discrimination of disease; but we must confess that at times diagnosis eludes us, not always because we are lacking in skill or in experience, but because our knowledge is still insufficient. Missed diagnoses are not to be regarded as errors. The medical museum and the post-mortem room offer proof that in many cases a missed diagnosis, often unavoidable, has occurred.

Our nomenclature is sometimes at fault, suggesting an artificial classification of disease into separate entities; thus, when an anatomical diagnostic term is used it tends to narrow our field of view, and we may fail to realize that disease may be a widespread process affecting the whole organism. Occasionally a diagnostic term may serve as an expedient for concealing ignorance. When we speak of a deficiency of hormones are we in fact more lucid than were our predecessors when they said a patient was suffering from the spleen?

Disease Without Symptoms.

Variations from the normal structure may occur without associated disturbances of function. The presence of unilateral kidney may remain unsuspected during the lifetime of the patient and be revealed for the first time in the post-mortem room: before the introduction of modern methods of genito-urinary investigation cases occurred in which the unilateral kidney was excised in the operating theatre with fatal results. The patient with a polycystic kidney may not present symptoms till he has reached middle age, and the analogous condition of congenital cystic liver may remain unsuspected till its increasing size creates a diagnostic problem.

A woman, aged 43, had an enormous liver, with cystic swellings that had been slowly developing for many years; tests for suspected echinococcus disease gave negative results; laparotomy revealed simple cystic disease of the liver.

Congenital morbus cordis may remain unsuspected, and I have known an absent interventricular septum to be found accidentally at a necropsy on an adult woman. Advanced cancer of the stomach may occur without the association of dyspeptic symptoms, and surgeons have demonstrated that patients whose stomachs have been removed may afterwards suffer little or no inconvenience.

In acquired disease compensatory changes, or encroachment on the physiological reserve, may mask the condition

*A paper read to the Bristol Division of the British Medical Association, on December 6th, 1929, and in part to the West Jewish Hospital Medical Society.

till routine examination brings it to light. School inspection reveals unsuspected mitral stenosis; medical officers examining recruits for the services find cases of aortic regurgitation compatible with apparent health and full activity. Coronary thrombosis presents a characteristic train of symptoms—pain, pyrexia, leucocytosis, and fall in blood pressure—but advanced coronary disease may be symptomless till sudden death occurs. Sometimes post-mortem examination in a case of sudden death reveals an unsuspected extensive pneumonic consolidation. A most surprising example of silent disease was in a woman six months pregnant, who died suddenly while mounting an omnibus. In her heart were found numerous large gummata replacing a great part of the myocardium.

The chief factor concerned in adaptation to structural change is time; abnormal changes coming on suddenly are more likely to produce symptoms than similar, or even more advanced, structural changes having a gradual onset. Thus a spontaneous pneumothorax generally presents dramatic signs, but I have seen three insidious cases complicating chronic phthisis in which the condition was discovered during routine examination in an out-patient clinic. Similarly, haemorrhage into the lung, or even a pneumonic exudate, may cause severe distress, but a slowly growing neoplasm may attain a large size without producing symptoms. Renal calculi can produce extreme destruction of one or both kidneys and their presence remain unsuspected until the onset of a terminal uraemia.

The Onset of Symptoms.

The period that may elapse before a structural change produces symptoms is inconstant, depending not only on the time factor just mentioned, but on the individual. A patient may have a large pleural effusion and still feel well; tumours may grow for varying periods in the silent areas of the brain, or in the thorax, before they produce irritative or pressure symptoms in adjacent tissues; gall-stones filling the gall-bladder may produce no symptoms, and sometimes, in cases of tumour of the bowel, symptoms may be long delayed. It is difficult to tell at what stage a large white kidney, or a small white contracting kidney, begins to produce symptoms. These, and like conditions, are occasionally found during routine examinations or accidentally in persons undergoing examination for the presence of other diseases.

A youth, aged 18, admitted to hospital with acute myelitis of the dorsal cord, died in a few days. At the necropsy an unsuspected empyema was found to have tracked behind the pleura into the extradural space, causing a pressure paraplegia. The initial lesion was probably caries of a dorsal vertebra.

A medical student examining his own blood in the course of his studies found a condition of myelaemia with 120,000 leucocytes per c.mm. Investigation showed that he had a large spleen.

Various Aids to Diagnosis.

While it is true that clinical pathology has extended our knowledge of the early stages of disease, its findings are not infallible, and if we rely on them too rigidly we may miss a diagnosis. A spirochaete, Klebs-Loeffler bacillus, a positive serological reaction, leucocytosis, leukaemia, etc., are diagnostic, but at times may occur apart from the disease of which they are characteristic. Diphtheria bacilli may be present without producing diphtheria; a Widal reaction is obtained long after the patient has had prophylactic inoculation; a positive Wassermann reaction may be found in quiescent syphilis.

Negative findings may have little diagnostic significance and lead to error; thus peritonitis and other suppurative conditions may occur without leucocytosis; blood cultures may be negative in infective endocarditis; agglutination reactions may be delayed or even absent in typhoid fever. Failure to find, for example, a malaria parasite or the entamoeba, or a positive Wassermann reaction, should not rule out a diagnosis of the conditions with which these are associated.

In many cases disturbances of function can be detected by biochemistry only when advanced structural lesions are present, but such investigation has helped the clinician to avoid error. It has enabled him to discriminate renal glycosuria, which formerly was treated as diabetes mellitus, often—because the patient was deprived of carbohydrates—with serious results. In patients suffering from vomiting, constipation, and abdominal distension, it has helped him to differentiate uraemic conditions from intestinal obstruction. Similarly radiography helps in the diagnosis of renal calculi and gall-stones, though negative findings are of less value. After all, radiography cannot replace the clinical examination, which supplies data necessary for a proper interpretation of shadows. Even instruments used in clinical medicine may serve to mislead the practitioner. How much less important than the experienced eye is the stethoscope in the examination of the chest in a toxaemic and partially asphyxiated bronchopneumonic child, or the thermometer in a severe apyrexial pneumonia? How misleading may be the information yielded by the sphygmomanometer in a case of arterial degeneration with low blood pressure!

Compensatory Adaptability; Cryptic Disease.

Chronic inflammatory changes in the kidneys or liver leading to fibrosis and shrinking are often unsuspected till the occurrence of a terminal uraemia, cerebral haemorrhage, or a fatal toxaemic coma.

A schoolgirl, aged 12, active and well, had a fit, and died in hospital a few days later. Necropsy revealed distorted, shrunken, white granular fibrotic kidneys and cardio-vascular hypertrophy.

A servant girl, aged 20, became unconscious and died from a large cerebral haemorrhage. She had contracted scarlet fever when she was 9, and suffered from chronic interstitial nephritis and cardio-vascular disease.

Is the diagnosis of such cases always overlooked? If the individual came for examination in the stage of apparent health could the condition be recognized? Occasionally, yes; but the possibility of effecting a diagnosis increases as the disease progresses. The urine does not always contain albumin, but the specific gravity decreases, cardio-vascular changes develop, and blood pressure rises; later, retinal changes appear. Biochemical tests for renal inefficiency are less helpful: wide variations from normal occur only in advanced stages. Moreover, the significance of such variations may be misinterpreted, as cardiac failure may produce a similar but temporary impairment of renal function.

The pre-ascitic stage of cirrhosis of the liver is, I think, most often diagnosed retrospectively; even the ascitic stage may be absent if the peritoneum is not extensively implicated in the fibrotic process, and the diagnosis may be missed till a fatal toxaemia or haemorrhage ensues.

A medical man, aged 50, suffered for over six years from intractable pruritus ani. Only after his death from cardiac failure was cirrhosis of the liver revealed.

A woman, aged 25, whilst at work became comatose and died in two days from extreme atrophic cirrhosis of the liver with splenomegaly but no ascites.

Cancer of the oesophagus may occur without producing dysphagia, and sometimes after it has perforated into a bronchus it is diagnosed as septic pneumonia. Similarly thoracic aneurysm may remain unsuspected for years.

Anomalous Symptoms.

In tracheal diphtheria without involvement of the fauces, a throat swab may give a negative finding. I have known cases in which the bacilli were found only in the sputum or in the vomitus. Nasal diphtheria may remain unrecognized and run a chronic course till an epidemic draws attention to the presence of a carrier.

A nurse complained of attacks of impending suffocation. She had low fever and a quick pulse, but the fauces were clear and throat swabs were negative. A tracheotomy became necessary, and in the discharge Klebs-Loeffler bacilli were found in abundance.

A fulminating type of infectious disease is often missed except in epidemics, and mild cases or ambulatory types may also escape notice. Whooping-cough in adults, owing to the absence of whooping, is often unsuspected.

A man, aged 54, suffered from intractable cough with no physical signs to account for it. After some weeks of unsuccessful treatment his grandchildren developed whooping-cough; it was then found that his blood picture showed a lymphocytosis.

Accompanying hypothyroidism is an important condition which I have not seen described since the late Dr. R. G. Hebb first directed my attention to it—namely, intestinal

atony. One case was subjected to operation, on the assumption that intestinal obstruction was present. Since then I have seen two similar cases, which were relieved by thyroid medication; in both of these radiograms showed enormous distension of the colon. I believe that milder grades of this condition are overlooked, and that many cases of abdominal distension and "pot-belly" in middle age are definitely improved by thyroid extract.

A woman, aged 56, was admitted to hospital with abdominal distension. She had a dry skin and coarse hair. The condition was attributed to a surgical lesion, and operation was advised. Laparotomy revealed a greatly extended large bowel, showing peristalsis, but no obstruction; the patient died six months later, and at the post-mortem examination I could find no abnormality except a completely atrophied thyroid gland.

Another condition sometimes associated with abnormal thyroid activity is intractable vomiting; in one such case thyroid medication put an end to vomiting, which for several months had been occurring frequently.

A woman, aged 46, had pyrexia, a rapid pulse, and frequent vomiting, unrelated to meals; the thyroid became prominent, and acetonuria developed. Rapid improvement followed the administration of iodine. Later the patient relapsed, but on being given iodine was improved once more.

This history raises the question whether the cases of severe vomiting which respond to tincture of iodine are of similar origin, and perhaps explains the failure of iodine in other cases.

The abdominal symptoms in hyperthyroidism may simulate cholelithiasis or appendicitis, and patients in whom this has happened have occasionally been subjected to operation.

Diagnosis Missed till Sequelae Appear.

I need hardly remind you of the dramatic revelation, by perforation or haemorrhage, of previously unsuspected peptic ulcer, or of the similar, though rarer, sequence in ambulatory typhoid fever. Equally familiar is the desquamation following scarlet fever which a few weeks previously had been diagnosed as tonsillitis; or the paralysis which recalls the history of sore throat, the diphtheritic nature of which was not suspected. A more recently discriminated condition is the Parkinsonian syndrome appearing in a patient not known to have suffered from encephalitis lethargica. Some such patients give a history of "influenza," and in general it would seem that, as with diphtheria, the mildness of the disease bears no relation to the incidence of sequels.

Delayed Physical Signs.

Central pneumonia, especially in children, is often puzzling till, as sometimes happens, the consolidation reaches the surface; in some such cases the symptoms suggest meningeal involvement, but lumbar puncture gives negative results. In one case a radiogram revealed a shadow centrally situated in the lung.

A girl, aged 8, was admitted to hospital with remittent pyrexia of from 100° to 103°, a quick pulse, and no characteristic physical signs. Paratyphoid fever, diphtheria, and miliary tuberculosis were all suspected in turn, but eventually all of them were ruled out. Following crepitations, which appeared about the third week, there developed definite signs of consolidation in the right axilla; a diagnosis of central pneumonia was established, and the patient was discharged two months after admission, though resolution was still incomplete.

Hodgkin's disease and chronic tuberculosis are examples of diseases which may remain undiagnosed, owing to the delayed development of their characteristic physical signs. When the lesions are confined to the thoracic or abdominal glands Hodgkin's disease may progress for months unrecognized unless a Pel-Ebstein temperature curve is present, while chronic abdominal tuberculosis may be present for a long time before it is detected. At the moment I have under observation a child who for seven months has had fever and debility; recently a few tubercle bacilli have been found in the stools, all previous attempts to find them having failed.

Incomplete History.

At times patients deliberately suppress facts; they may deny a history of gonorrhoea, and diagnosis is difficult, owing to the fact that the gonococcus may for long periods remain latent in the body. In two of my cases of chronic arthritis the gonococcus was cultivated from the prostatic secretion over twenty-three years after the original lesion.

A man, aged 62, had been treated over twenty years for "rheumatic gout," which had led to severe crippling. Notwithstanding his denial of venereal infection I examined the prostatic secretion and obtained a culture of gonococcus; he then remembered having been infected thirty years previously.

When a patient gives a history of having lived abroad the fact should receive due attention. The malaria parasite dies out after a time, but *Entamoeba histolytica* may remain potentially active for indefinite periods. In cases of liver abscess, therefore, even if no amoebae or cysts are found in the stools, it is advisable, by giving a course of emetine, to test a diagnosis suggested by the history. Again, an unexplained pyrexia with a suggestive history may respond to treatment with quinine.

A man, aged 59, had to retire from an important post on account of an illness diagnosed as "pernicious anaemia." He mentioned casually that he had had dysentery many years previously; examination of his stools revealed active entamoebae, and treatment led to complete recovery.

Due attention must be paid to a history of cancer or other growth excised, no matter how long ago. In cases of pain arising from metastasis in the spine I have known diagnosis to be delayed because of failure to appreciate the significance of a history of breast amputation carried out many years previously. In two cases of melanotic cancer metastasis occurred fifteen years after excision of the eyeball—an exceptionally long interval considering the type of growth.

One Disease Simulating Another; Masked Disease.

Albuminuria, with or without haematuria, due to calculus is sometimes diagnosed as nephritis, especially when the calculus is of uric acid, which does not show on radiograms.

A girl, aged 6, with occasional slight albuminuria, had been kept in bed for two years, her illness being diagnosed as nephritis. She was admitted to hospital, and the calculus, revealed by *x* rays, was removed; there had been no pain.

Bacilluria which does not respond to treatment often disguises the presence of stone or tuberculosis, or even cancer. A simple pleural effusion may result from a more serious subdiaphragmatic lesion.

A man was admitted to hospital with pain and tenderness in the loin, and fever; he had a leucocytosis. A serous pleural effusion found on the same side as the pain, seemed insufficient to account for the symptoms, and further exploratory puncture in the loin revealed a perinephric abscess, which was evacuated.

Difficulty is apt to arise in acute leukaemia—by no means a rare disease; the haemorrhages from the gums and elsewhere have been mistaken for scurvy, gastric ulcer, and in one case, at first, for placenta praevia. In cases of acute leukaemia, which end fatally in a few days or weeks, there are no obvious glandular enlargements.

Cases which Remain Undiagnosed.

I have records of several cases of severe illness, generally with pyrexia, which have resisted all attempts at diagnosis, but the patients have completely recovered. Sometimes all the practitioner can do is to record his observations of a case, hoping that in the light of later experience he may be able to interpret these observations. The following is an example of a case of severe illness the nature of which has always remained in doubt.

A woman, aged 33, suffered with rigors, pyrexia, and a quick pulse, following "stomach-ache" and nausea. Appendicectomy was performed, but the symptoms persisted; at times the temperature was 103°. The urine was normal and blood cultures were sterile; but there was a leucocytosis (20,000). Paratyphoid fever, bacilluria, and septicaemia were eliminated, and tentatively a diagnosis of pylephlebitis was made, as there was slight icterus and a tender liver. In six weeks the temperature subsided, and after several exacerbations the patient recovered and remained in good health.

Diagnosis not Revealed by Necropsy.

Occasionally, particularly in children, even necropsy fails to advance the diagnosis. I have seen several cases of children admitted to hospital with symptoms suggesting encephalitis, but post-mortem examination has revealed no evidence of this disease, or of any other. Man, after

all, presents physiological as well as anatomical problems, and it is only the latter that are dealt with in the post-mortem room. The following case raises the question whether a man can die of fright.

A Sikh visiting England was treated in the casualty room for a Colles's fracture. He was leaving the hospital when he dropped dead at the exit. The most careful examination revealed no cause of death. He was a well-developed man in the prime of life.

Conclusions.

In my survey I have said nothing about middle-ear disease in children, or of gastric crises; nor have I attempted to deal with syphilis, which I sometimes think can simulate nearly every disease.

It has been said that medicine is made up of common sense and experience. The former is essential if one is to benefit from the latter. The practitioner is most likely to arrive at a correct diagnosis by means of an orderly method of examination, intelligent use of ancillary means of investigation, avoidance of bias, and the application of general principles derived from his own experience. If for a moment I may be didactic, I would say, Do not be satisfied with a diagnosis unless it explains all the symptoms, and if you have any doubt do not hesitate to say so. Even in the presence of the most difficult case we are not helpless; the whole of our art is not in diagnosis—certainly not from the patient's point of view. The patient seeks relief from his symptoms, and I recall the remarks made by the late Professor Leech in introducing a course of therapeutics: "Relieve the symptoms, make a diagnosis, treat the disease."

RADIOLOGICAL DIAGNOSIS OF THE DISEASED APPENDIX.

BY

A. ORLIANSKY, M.D.GENEVA, M.R.C.S.ENG., L.R.C.P.LOND., D.M.R.E.CAMB.,

ASSISTANT RADIOLOGIST, FRENCH HOSPITAL, LONDON.

THE filling of the appendix with barium was considered by some workers as an exceptional, or even an abnormal, phenomenon only a few years ago. Thus F. M. Groedel, in 1921, wrote: "The appendix does not fill easily with barium meal, and, with the majority of radiologists, I consider at the present moment the radiological visualization of the appendix as an abnormality, or at least as an exception." A few years later the opinion became current that with skill and care the appendix could be visualized in 90 per cent. of cases during the usual routine examination.

The visualization of the appendix probably depends largely on the preparation of the patient; no amount of training and technical skill can enable the examiner to visualize an appendix if the lumen is filled with faecal matter. It is therefore of the utmost importance, in all

FIG. 1.—Case 1. Seventy-two hours after ingestion.

cases where a diseased appendix is suspected, to have the bowels thoroughly evacuated by a suitable purgative before the *x*-ray examination. Eau de Châtel Guyon or eau de Gubler are supposed to be particularly effective in this respect, but castor oil or Epsom salts are probably equally good. Alois Czepa advises the administration of the barium meal mixed with two teaspoonfuls of Epsom salts. With this technique the appendix is visualized after six to twenty-four hours, but the best time is between ten and twelve hours, since the ileum is as a rule empty by then and does not overlap the caecal region, while the caecum is well filled.

Mobility of the Appendix.—The normal appendix is freely movable, either spontaneously or on manipulation; of course, the diseased appendix is not necessarily fixed. Among the different kinds of fixed appendices there are two types giving rise to definite clinical pictures. (*a*) There is the appendix fixed all along the caecal wall, forming, so to speak, an integral part of the caecum. It is obvious that this appendix is stretched when the caecum fills, and may give rise to severe pain at the moment when this happens; the pain subsides with the emptying of the caecum. Such an appendix, overlapped by the shadow of the caecum, may occasionally become visible after the caecum has emptied itself. (*b*) Then there is the appendix only the tip of which is fixed to the pelvic wall. In such cases there is no pain so long as the caecum is full, heavy, and consequently situated low in the pelvis. But as soon as such a caecum empties itself it ascends and drags the appendix with it, thus causing pain.

CASE I.

A boy, aged 8, had about six attacks of abdominal pain during the eighteen months preceding November, 1928. The attacks lasted from half an hour to several days; during them the temperature rose, the breath was foul, and the child became of a pale greenish colour. The pain disappeared after defaecation. The clinical diagnosis made was chronic appendicitis.

The *x*-ray examination (illustrated in Figs. 1 and 2) gave evidence of hypersecretion of the stomach, with poor filling of the duodenal cap. The appendix became visible at four hours; throughout the whole examination (ninety-six hours) it remained

FIG. 2.—Case 1. Ninety-six hours after ingestion and twenty-four hours after a dose of $MgSO_4$.

in exactly the same position and could not be displaced by manipulation, giving the impression of being fixed to the wall of the caecum. It was slightly tender to pressure. Its canal is seen to be dilated, and it remained filled after a dose of Epsom salts. The radiological diagnosis was a chronically inflamed and dilated appendix fixed to the caecum. An operation and histological examination of the removed appendix confirmed the radiological diagnosis.

Appendicular adhesions may alter the shape and position of the caecum, which may appear to be deformed, displaced upwards, etc. Displacement and alteration of the shape of the caecum, descending colon, and lower ileum may be caused by large and encapsulated appendicular abscesses, but, of course, an abscess of any other origin in the region of the caecum would give rise to similar appearances. In one case, in which an acute attack of

appendicitis (in the course of a subchronic appendicitis) began during the *x*-ray examination (diagnosis confirmed by operation), the caecum showed considerable spasticity and was much deformed; such spasticity may occasionally also be observed in chronic appendicitis.

Dilatation of the appendicular canal is a very important sign, and was present in the case just mentioned. The club-like dilatation of the distal end of the appendicular canal is an almost certain sign of chronic appendicitis.

CASE II.

A married woman, aged 41, had been suffering from attacks of pain in the lower abdomen during the five months ending

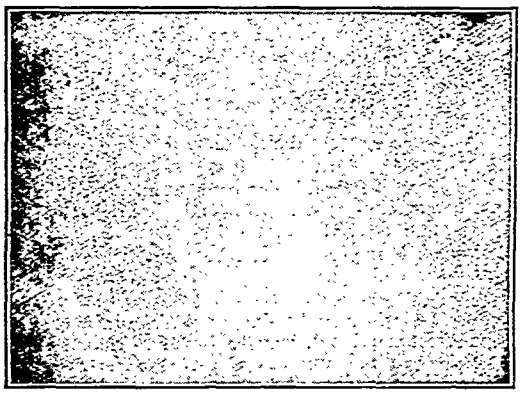

FIG. 3.—Case II. Twenty-four hours after ingestion.

April, 1929. The *x*-ray examination (Fig. 3) showed a long, *dilated appendix with club-like end*. The appendix seemed to be fixed to the caecum, and was tender to pressure. The radiological diagnosis was chronic appendicitis.

Three weeks later the patient was suddenly taken ill with symptoms of acute appendicitis, and was operated on by Mr. Cairns Forsyth on May 10th. The appendix was found much dilated and adherent to the caecum; it contained a great number of grape and fruit seeds, and its walls were much thinned.

The region of the diseased appendix is as a rule more or less tender to pressure. Quite frequently the patient himself, when asked to show the most tender spot, places his finger over the appendicular region. The tender spot changes its position when the appendix is displaced through manipulation, but, in the absence of other confirmatory signs, not much importance can be attached to tenderness of the appendicular region.

Caecal stasis, in the form of a mass of barium remaining in the caecum for several days after the rest of the colon has emptied itself, is supposed to be one of the signs of chronic appendicitis; but, as a matter of fact, caecal stasis is frequently found in patients with quite normal appendices.

CASE III.

An unmarried woman, aged 21, had suffered for a few years with pain in the right hypochrondium and hypogastrium. At the *x*-ray examination the appendix was not seen and the appendicular region was not tender; but seventy-two hours after the ingestion there was a noticeable mass of barium in the caecum, and at ninety-six hours barium was still present there and at the hepatic flexure. An operation revealed Jackson's membrane, Lane's first kink, and two strong fibrous bands attached to the outer side of the caecum. The appendix was normal. Adhesions between the ascending and the transverse colon at the hepatic flexure were freed, the bands were severed, appendicectomy was performed, and a good recovery ensued.

In this case the caecal stasis was undoubtedly caused by adhesions and bands, but the appendix was normal. When we find caecal stasis combined with a diseased appendix it is difficult to say which is the primary and which the secondary condition. *A diseased appendix may* affect the adjoining caecum, but caecal stasis may in turn interfere with the emptying of the appendix, and result in appendicular stasis, leading eventually to chronic appendicitis.

CASE IV.

An unmarried woman, aged 22, had an operation eight years ago for retroversion of the uterus, and since then has suffered from sudden attacks of diarrhoea, which come on irregularly and are caused by certain foods (eggs, fish), by cold, emotional disturbances, etc. In the intervals between attacks the bowels were rather loose. The *x*-ray examination (Figs. 4 and 5) showed a well-filled appendix, which was tender to pressure and not fixed. The caecum and appendix remained filled 120 hours after ingestion, the remainder of the colon having already emptied itself three days before. The appendix was still filled 144 hours after an effective dose of castor oil. The radiological diagnosis was caeco-appendicular stasis and probably diseased appendix. An operation is still under consideration; in the meantime the patient is keeping fairly well under medical treatment.

FIG. 4.—Case IV. One hundred and twenty hours after ingestion.

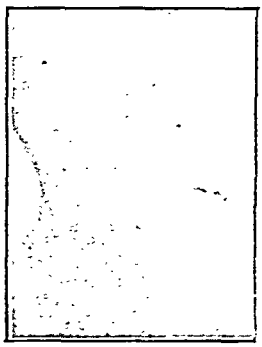

FIG. 5.—Case IV. One hundred and forty-four hours after ingestion and twenty-four hours after a dose of castor oil.

In this case the attacks of diarrhoea and the loose stools are undoubtedly caused by the caecal stasis, which keeps up an irritation of the colon; but it is impossible to say which of the two, the appendicular stasis or the caecal stasis, is the primary and which the secondary condition. This is a very important question, since if the appendicular stasis is secondary to the caecal stasis appendicectomy will not bring about a definite cure.

This case brings us to another important sign of [illegible] appendicitis—namely, appendicular stasis, indicated by the presence of barium in the appendix after the caecum has emptied itself. We must admit, however, that even a severe appendicular stasis, resisting repeated administrations of purgatives, does not necessarily indicate a chronic appendicitis in the absence of other confirmatory clinical signs and data. I have seen an appendix still containing barium six days after administration of the barium meal, and this in spite of two doses of castor oil and repeated enemata. In this case there was not the slightest likelihood of a chronic appendicitis. It is probable that barium is partly liable to be retained in the narrow appendicular lumen. If the loops are [illegible] so that a sluggish but not necessarily diseased appendix would retain it for a considerable time.

The retention of the barium residue in the appendix may be favoured by a partial stenosis of the proximal part of the lumen of the appendix. *The liquid barium penetrates* through the narrowed part of the appendix into the distal end, but there it thickens and hardens, so that the appendix becomes unable to expel it. This probably happened in the following case.

CASE V.

An unmarried woman, aged 25, had been suffering from abdominal pain for about six months, the last period of constipation followed by diarrhoeic attacks. An *x*-ray examination was made after purgation by a dose of Epsom salts, followed twenty-four hours later by the administration of a barium meal mixed with another dose of Epsom salts. The appendix was movable and slightly tender to pressure. It remained filled for ninety-six hours after the administration of the meal, and in spite of a dose of castor oil. The radiological diagnosis was chronic appendicitis.

At the operation there was revealed a long appendix curved on itself with no adhesions. On *x*-ray examination of the removed appendix the distal three-quarters of the appendix showed broad, dense barium shadows and the regular outline of the appendicular canal; at the junction of the proximal quarter and the distal three-quarters of the appendix there was a narrowing of the

FIG. 6.—Case V. Radiography of the removed appendix.

appendicular lumen. (See Fig. 6.) The abdominal symptoms disappeared after the operation, and there has been no recurrence during fourteen months.

Appendicular stasis is sometimes observed in chronic inflammatory conditions of the right tube or ovary, with or without involvement of the appendix.

CASE VI.

A married woman, aged 38, suffered from sterility and frequent abdominal pain, mostly on the right side. At the *x*-ray examination the appendicular region, particularly the appendix itself, was found to be tender to pressure, and there was appendicular stasis up to seventy-two hours after ingestion of the meal. A diagnosis was made of chronic appendicitis with involvement of the right tube and ovary.

An operation was performed, and the appendix was found lying in a kind of pocket formed by fibrous adhesions around the right tube; the appendix itself was free. Histological examination of the removed appendix showed increase of the fibrous tissue with signs of chronic inflammatory reaction. The operative findings are rather in favour of a chronic tubo-ovarian inflammatory condition with secondary involvement of the appendix.

In the next case, in spite of the inflammation of the right ovary, the appendix was not involved, but it showed stasis through sluggishness, probably caused by its proximity to the diseased ovary.

CASE VII.

A married woman, aged 30, had been suffering for some time from constipation and headaches. Five weeks before examination she had nausea and an attack of pain on the right side of the abdomen. Constipation was present, but the clinical and vaginal examinations were negative.

The *x*-ray examination revealed that the appendix remained filled ninety-six hours after ingestion, though the colon and caecum had expelled the barium forty-eight hours after ingestion. The appendix was not tender, but there was a definite tender point below it, and the conclusion was reached that there was a chronic tubo-ovarian inflammatory condition of the right side, but the appendix was probably not diseased.

At the operation both ovaries were found to be adherent to the abdominal wall. The appendix was normal. Adhesions were freed, and appendicectomy was performed. Recovery was uneventful, and there was no recurrence of symptoms during nine months.

The length of the appendix may range from two to twelve inches; occasionally it looks very short, and this may be due to pathological changes within the appendix or to a kink preventing further penetration of the barium. In one case a very short appendix was found in a man who had been operated on for appendicitis twenty-eight years previously. The appendix was removed, but obviously a part of it was left, and this fragment, about three-quarters of an inch long, was very tender to pressure. There were also clinical symptoms of chronic appendicitis. Incidentally the radiological examination revealed the presence of a duodenal ulcer, and of pericholecystitis. It is quite possible that the affection of the duodenum and gall-bladder were secondary to the chronic appendicitis.

The non-filling of the appendix can be interpreted as a sign of disease only when it is impossible to visualize the organ after repeated purgation, followed each time by the administration of barium. In such cases the non-filling of the appendix suggests an obliteration of its lumen, or kinks, or dragging. It may be due also to a retrocaecal position of the appendix, whereby the shadow of the appendix is overlapped by the filled caecum, the caecum and appendix emptying simultaneously.

These are the most frequent radiological signs of the diseased appendix. Further research and experience will probably reveal other signs and at the same time enable us to interpret more accurately the signs described.

SUMMARY.

1. The appendix can be visualized radiologically in about 90 per cent. of cases. Frequently the appendix is visualized only after thorough purgation of the bowels.

2. Two different types of fixed appendix are described: (*a*) The appendix fixed to the caecal wall; stretching of the fixed appendix through filling of the caecum causes pain; the pain subsides when the caecum empties. (*b*) The appendix with the tip only fixed to the pelvic wall; emptying, with consequent rise of the caecum, causes pain through dragging on the fixed appendix.

3. Spasticity of the caecum may be observed during an attack of acute appendicitis, but occasionally also in chronic disease.

4. The dilated appendicular canal, and particularly the club-like dilatation of the distal end of the appendix, are almost certain signs of a diseased appendix.

5. Not much importance can be attached to tenderness of the visualized appendix in the absence of other confirmatory signs and symptoms of appendicular disease.

6. Caecal stasis may be due to a chronic appendicitis, but, on the other hand, may be found in cases of normal appendices. In the presence of caecal stasis and chronic appendicitis, it is difficult to say which of the two is the primary and which the secondary condition. In cases of primary caecal stasis appendicectomy would not cure the caecal stasis.

7. Appendicular stasis is suggestive of chronic appendicitis only in the presence of other confirmatory radiological signs and clinical symptoms of appendicitis. Stasis persisting after the administration of a purgative is sometimes caused by a partial, localized stenosis of the appendicular canal; the fluid barium penetrates through the narrowed lumen, but cannot be expelled after it has thickened and hardened through absorption of fluid.

8. Appendicular stasis is sometimes seen in chronic tubo-ovarian inflammatory conditions, with or without inflammatory involvement of the appendix.

9. The short appendix may be due either to pathological changes within the appendicular canal or to kinks or adhesions of the appendix.

10. The non-filling of the appendix can be interpreted as a pathological sign only in cases where the appendix cannot be visualized after repeated purgation, each purgation being followed by a barium meal.

I wish to express my thanks to the honorary radiologist of the French Hospital, Dr. Hernaman-Johnson, to the surgeon Mr. J. Cairns Forsyth, Mr. R. Rowe, and Mr. C. Burnham, and to Dr. J. Moore, for permission to publish some of the cases mentioned in this paper.

AN OUTBREAK OF PSITTACOSIS.

BY

MARY C. RADFORD, M.D.LOND.,

OXFORD.

ON December 21st, 1929, a green parrot was given to the two sons (aged 13) of Dr. and Mrs. M. It arrived ill, which was attributed to its having been sent by train on a very cold day. It died on December 30th.

Eight people were more or less in contact with the bird —Dr. and Mrs. M., their two boys, the cook, the gardener, a nephew of Dr. M.'s, and a friend who spent Christmas with them. Of these, the first four and the friend handled the bird; the cook went into its room, and the gardener cleaned the cage and took the dead bird away after Mrs. M. had put it in a tin box. He was told to dispose of it, but instead he put it in the shed where he worked and left it there. It was afterwards found and buried by Dr. M. On December 30th the nephew arrived to convalesce after an operation, and he spent some hours in the room in which the parrot had died. Of these people, Mrs. M., the cook, the nephew, the gardener, and the friend all became dangerously ill; the other three escaped. Only two of these five persons became ill before the party broke up, and so it happened that all the patients came under different doctors and the epidemic character of the outbreak was not at first realized.

CASE I.

In this case there was at first an apparently obvious diagnosis of the recurrence of a long-standing pyelitis. The patient, Mrs. M., felt unwell on January 5th, and on January 7th she had a rigor and went to bed with a temperature of 104° F. She had some backache and felt "very cold across her back," and had extremely severe headache. There was no sore throat, nor were there any pulmonary or abdominal symptoms. On January 9th she was seen by Dr. Smith of Henley, who has kindly assisted me in drawing up the account of the first part of the illness.

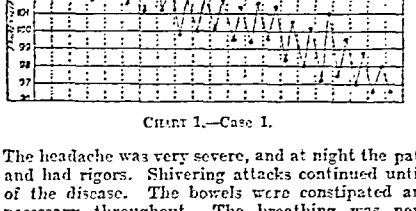

CHART 1.—Case 1.

The fever continued at about 104° in the evening, falling to about 102° in the morning after profuse sweating. The headache was very severe, and at night the patient was delirious and had rigors. Shivering attacks continued until the seventh day of the disease. The bowels were constipated and aperients were necessary throughout. The breathing was never suggestive of pulmonary complications. The pulse was always slow in proportion to the temperature. The urine was turbid and contained mucus and pus with a small quantity of albumin (accounted for by the pus). The right kidney was never really tender when palpated, but there was possibly a little tenderness over the right ureter.

I saw the patient on January 15th, when the fever was beginning to abate. There were no signs in the lungs, nor was there tenderness over the region of the kidney. The pulse was poor in quality and the heart sounds were rather feeble. The pus in the urine was about the same in quantity as on other occasions when I had seen Mrs. M. with an attack of fever and rigors due to an exacerbation of her kidney condition. She was obviously beginning to improve. It was not until the continuation of the fever in spite of the absence of tenderness over the kidney cast doubts on the diagnosis of pyelitis, and the news came of the illness of the other contacts, that we diagnosed the case as one of psittacosis, and blood was sent to the London Hospital for examination. The clinical diagnosis was confirmed by Dr. Robert Hutchison, who saw Case v in London.

The patient made a slow but uninterrupted recovery, the temperature becoming normal by January 25th (the nineteenth day of the disease). A few crepitations appeared at the bases of both lungs on January 21st, but these were probably due to decubitus. There was marked weakness and prostration throughout the illness. On January 22nd I did a leucocyte count, which was 26,500 per c.mm.; by January 23th it had fallen to 13,000. The spleen was never palpable. The course of the fever is shown on the chart.

CASE II.

This patient, the cook, aged 65, felt ill on January 7th, and went to bed with a temperature of 104° F. on January 13th. She continued to feel very ill with fever up to 105°, delirium, great weakness, and twitchings. She was removed to Henley Infirmary on January 12th under the care of Dr. Smith, who sends the following notes.

"She was flushed, had an evening temperature of 102°, with bronchial catarrh, and some crepitations at both bases. She was sometimes incontinent (urine) and somewhat delirious. There was some albumin in the urine. She had a very furred tongue, and gave one the impression that she was suffering from paratyphoid, but a specimen of blood gave negative results. Her temperature generally fell in the morning to 100°, and after three days it became normal, and remained so. Her tongue cleared very gradually, but she continued to be occasionally incontinent (sometimes both faeces and urine) up till January 25th. Since then she has made a good recovery."

CASE III.

The patient, aged 43, was the nephew, who had visited Dr. and Mrs. M. on December 30th, to convalesce after an operation for chronic appendicitis. He returned to Oxford on January 7th, and saw Dr. Frankland West on January 10th. Dr. Frankland West reports as follows.

Mr. M. complained of malaise and a raised temperature; during the first three days of his illness there were no special symptoms beyond the raised temperature, which, by the third day, was maintained at between 102° and 103° F. Respirations were normal and the pulse rate was between 84 and 90. The patient made no complaint of abdominal discomfort, and I could feel nothing abnormal in the abdomen. The chest was clear. High fever of a remittent type continued, the tongue became coated, the patient vomited on one or two occasions, completely lost his appetite, and was constipated. But beyond the high fever and the obvious toxaemia there were no signs or symptoms.

On the fourth day of the illness there were several loose actions of the bowels, the motions being of the pea-soup type. The patient began to be drowsy. At this stage he was sent into a nursing home. The high remittent fever, the comparatively slow pulse, the drowsiness, and the appearance of the stools strongly suggested that the disease was of the enteric group. The stools continued to be loose and offensive; the fever remained at a high level, and on the sixth day of the illness there were fine moist sounds to be heard over a considerable area of the left chest in front and at the back; the bases of the lungs were clear. The respiratory rate was not, however, raised at this stage.

On the following day (the eighth day) the respiratory rate rose rapidly from about 24 to 40 per minute. There were now moist sounds to be heard on both sides of the chest; these were best heard in front. The patient had some cough, with but little expectoration, and that was of the simple catarrhal type. During the next three days the respirations rose to 36 to 48 per minute; the pulse rate was 90 to 130 per minute; the patient was very drowsy and in a state of more or less persistent low muttering delirium; he had fine muscular twitchings.

On the eleventh day a general improvement set in. The temperature fell to 102° maximum, and the pulse and respirations fell to 100 and 32 respectively. From this time onwards there was no marked feature of the case beyond the general resolution of the fever, and, correspondingly, of the pulse rate, and the chest signs rapidly cleared up. By the sixteenth day of the illness the patient was convalescent.

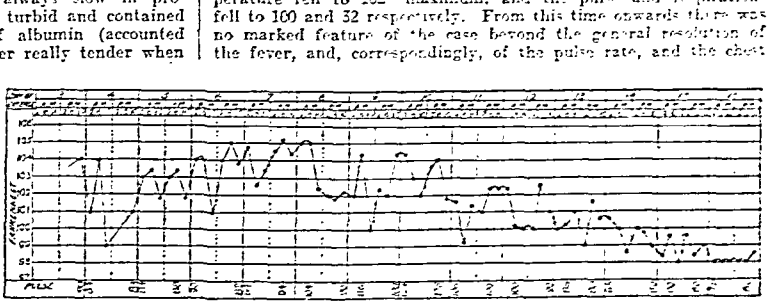

CHART 2.—Case 3.

The main features of the case were as follows: (1) the comparatively rapid onset of the fever and toxaemia; (2) the marked toxaemia, though the patient did not complain of headache; (3) the development of pneumonic involvement late in the disease —that is, about the seventh or eighth day; (4) the short duration of the critical stage—that is, from the seventh to the eleventh day; (5) the comparatively rapid resolution of the fever after the eleventh day of the disease; (6) the absence of abdominal pain or discomfort, and of physical signs in the abdomen; (7) the absence of albumin from the urine, except a slight amount in a

highly concentrated urine during the height of the fever; (8) the inconclusive Widal reactions of the serum; (9) the negative blood culture; (10) the failure to isolate organisms of the enteric or dysentery group from the stools; (11) the negative report upon the sputum.

CASE IV.

(Report by Dr. E. L. Elliott.)

On January 17th the patient, a gardener, aged 56, sought my advice for general malaise. He had been out of sorts for three or four days, but had been able to carry on his work. I found him with a temperature of 101° F., and ordered him to bed. For the first four days the temperature was raised, varying from 99° to 101°, and the pulse was slightly intermittent. During this time there was sleeplessness and low delirium, and the patient had some rigors followed by profuse sweating. He was seriously ill, and I considered a fatal termination a possibility. He developed a left-sided pneumonia of the lobar type, but without the violent respiratory symptoms of the pneumococcal form of that disease; the cough was never severe, and there was no sputum till January 27th, when yellow frothy muco-purulent sputum was brought up. The respiration rate was not markedly raised, nor was breathing difficult. The pulse rate was on the low side, usually below 100, and during the first week the cardiac action gave some cause for anxiety. The pulse was weak and the heart sounds were feeble. For the heart condition he was given digitalis.

On January 26th he was not markedly ill, the temperature was normal, and the pulse 96. He looked as if he had passed through an illness; the tongue was furred but beginning to clean at the edges; there was no sore throat and no rash. The heart was not enlarged, and its action was not abnormal. The left lower lobe gave a dull note, and coarse crepitations were to be heard over its whole extent. There was no evidence of pleurisy or of effusion, and there was no distress on taking a deep breath. The abdominal organs were normal; neither spleen nor liver could be felt, and though the bowels had been freely open they had not been abnormal. The blood gave no reaction to any of the typhoid or dysentery group, including *B. acertrycke* (Hutton) and *B. abortus* (Bang).

On January 30th the condition was much improved; there was still an impaired note at the left base, and fairly copious sputum. The improvement was very marked.

CASE V.

Miss F. was likewise very ill, but as she was seen in consultation by Dr. Robert Hutchison he will no doubt publish a report of the case later in his own series.

The outstanding features of the attack seem to be (*a*) the high infectivity of the disease from the bird, five out of eight contacts developing it; (*b*) the absence of a single case of infection from a human being; and (*c*) the extreme severity of the illness.

Two of the patients had symptoms suggestive of typhoid fever; three had lung symptoms, but none showed the solid condition of the lung described by Dr. Thomson at Birmingham.

I am most grateful to all the other doctors concerned for their kindness in providing me with details of the cases reported in this paper.

TREATMENT OF PERNICIOUS ANAEMIA WITH DESICCATED HOG'S STOMACH.

BY

ARNOLD RENSHAW, M.D., D.P.H.,

PATHOLOGIST TO ANCOATS HOSPITAL; BACTERIOLOGIST TO THE ROYAL EYE HOSPITAL, MANCHESTER.

IT is believed that the following record will be of interest in view of the severe relapse which occurred while the patient was on liver treatment and the subsequent recovery resulting from the administration of desiccated hog's stomach.

The patient, a man aged 52, was first seen by me on June 30th, 1924, for the examination of his blood condition, a diagnosis of pernicious anaemia having been made some time previously. On this occasion the blood count was as follows:

Red blood cells (per c.mm.)	1,700,000
White blood cells (per c.mm.)	6,200
Haemoglobin	40 per cent.
Colour index	1.17
Differential count:	
Polymorphonuclears	68 per cent.
Small mononuclears	21 "
Large mononuclears	3 "
Transitional mononuclears	4 "
Eosinophils	1 "

The film showed marked poikilocytosis and anisocytosis, also granular basophilic degeneration; one nucleated red cell was seen; no parasites.

I saw him on several subsequent occasions during the following years, and he was also treated medically in Germany. The diagnosis was frequently confirmed by ample blood counts and by clinical examination. His red blood cells were rarely more than 3,500,000, and his colour index was usually above 1.

In June, 1927, he became seriously ill and received medical treatment in Germany. This treatment took the form of several blood transfusions and the application of a diet chiefly composed of the yolk of eggs and orange juice, and was successful for a time. His blood count before treatment was: red blood cells 1,000,000 per c.mm., white blood cells 1,300, haemoglobin 30 per cent. Six months later, in December, 1927, he came to see me, and the count was: red blood cells 3,330,000, white blood cells 6,500, haemoglobin 84 per cent., and colour index 1.23.

Treatment by means of liver and liver extracts was duly tried in this case, but did not appear to bring the improvement met with so frequently in other cases of pernicious anaemia. At the commencement of his last relapse he had tried liver extract as made by several different reputable firms, but he was steadily getting worse. During this period he was out of my immediate observation, but he again came to see me on October 3rd, 1929. He was then in an extremely exhausted condition, and his blood count was:

Red blood cells (per c.mm.)	1,210,000
White blood cells (per c.mm.)	3,000
Haemoglobin	30 per cent.
Colour index	1.25
Differential count:	
Polymorphonuclears	46 per cent.
Small mononuclears	33 "
Large mononuclears	8 "
Transitional mononuclears	4 "
Mast cells	4 "

A few macrocytes, microcytes, and poikilocytes were present.

I wrote to his medical attendant that I regarded him as extremely ill, and that unless some drastic change could be effected he would die. I suggested that a transfusion be done, and also pointed out the recent work of Dr. Sharp, director of the Department of Experimental Medicine of Parke, Davis and Co., in regard to the administration of desiccated hog's stomach.

His medical attendant agreed with me as to the desperate nature of the patient's condition. The patient was very loath to have any further blood transfusions in view of the number he had had in Germany, and a very unpleasant experience he had had from receiving a few cubic centimetres of blood not of his own group. Consequently the blood transfusion was postponed temporarily. Treatment with another liver extract was continued, and the administration of glycerinated raw pig's stomach was tried. The condition, however, became worse, and a blood transfusion (140 c.cm.) was given on November 9th. This helped the patient a little, but the pulse was still rapid (120) and oedema in the legs was present forty-eight hours afterwards.

On November 16th the blood count was:

Red blood cells (per c.mm.)	985,000
White blood cells (per c.mm.)	3,600
Haemoglobin	22 per cent.
Colour index	1.22
Differential count:	
Polymorphonuclears	42.0 per cent.
Small mononuclears	41.5 "
Large mononuclears	13.0 "
Transitional mononuclears	0.5 "
Mast cells	1.0 "
Eosinophils	2.0 "

The red blood cells showed variation in size and shape; there were no nucleated cells.

I got into touch with Parke, Davis and Co., who promptly sent me experimental supplies of desiccated hog's stomach (ventriculin), so that this method of treatment might be tried.

At the commencement of treatment with hog's stomach the patient was in an exhausted condition; he was extremely anaemic, the lips were blanched, and the conjunctivae very pale. The spleen was enlarged two fingerbreadths below the costal margin, and the liver was also firm and enlarged. The pulse was 120 per minute with the patient in bed, and there was a fair amount of oedema in the feet. The tongue was very furred. Albuminuria also was present.

The first administration of hog's stomach consisted of 7.5 grams daily, and after a day or two the dose was increased to 15 grams. On January 13th, 1930, the dose was further increased to 20 grams. This treatment has been continued with only an intermission of a day or so up to the present time. After a few days the patient's condition improved considerably, but the blood count did not show the same improvement. Since then the improvement has been rapid and the patient is up and able to go out of doors. The spleen is not palpable and the liver is much improved. Albuminuria is still present, but there is no oedema. The pulse is now normal (72) except after exertion such as going upstairs,

when it rises to 84. The tongue is clean and the appetite good. The patient is putting on weight and mentally he is bright and alert. He has been able to attend at my consulting rooms for blood counts. The following counts will demonstrate the progress made. On November 30th, 1929, a few days after commencement of treatment with ventriculin, the blood count was as follows:

Red blood cells (per c.mm.)	830,000
White blood cells (per c.mm.)	2,000
Haemoglobin	20 per cent.
Colour index	1.2
Differential count:	
Polymorphonuclears	53 per cent.
Small mononuclears	42 ,,
Large mononuclears	3 ,,
Eosinophils	1 ,,
Megaloblasts	1 ,,

Poikilocytes and anisocytes were present. Eve's halometer reading = 3.7.

On January 6th, 1930, the patient's condition showed great improvement. A blood count was as follows:

Red blood cells (per c.mm.)	2,100,000
White blood cells (per c.mm.)	5,500
Haemoglobin (Haldane)	38 per cent.
Haemoglobin (Dare)	35 ,,
Colour index	0.83
Differential count:	
Polymorphonuclears	61.5 per cent.
Small mononuclears	32.5 ,,
Large mononuclears	3.5 ,,
Mast cells	0.5 ,,
Eosinophils	2.0 ,,

The red blood cells show variation in size and shape. No nucleated red cells were seen, and no reticulocytes. Halometer reading = 3.8. The blood count on January 20th was as follows:

Red blood cells (per c.mm.)	2,670,000
White blood cells (per c.mm.)	6,200
Haemoglobin (Haldane)	64 per cent.
Haemoglobin (Dare)	60 ,,
Colour index	1.19
Differential count:	
Polymorphonuclears	71.6 per cent.
Small mononuclears	24.4 ,,
Large mononuclears	2.4 ,,
Transitional mononuclears	0.4 ,,
Eosinophils	0.4 ,,
Mast cells	0.8 ,,

The red blood cells show variation in size and shape. No nucleated red cells were seen, and no reticulocytes. The following was the result of a count taken on January 27th:

Red blood cells (per c.mm.)	3,600,000
White blood cells (per c.mm.)	5,500
Haemoglobin (Haldane)	74 per cent.
Haemoglobin (Dare)	71 ,,
Colour index	1.03
Differential count:	
Polymorphonuclears	65.5 per cent.
Small mononuclears	28.0 ,,
Large mononuclears	0.5 ,,
Transitional mononuclears	5.5 ,,
Eosinophils	0.5 ,,

PROBABLE SEPTICAEMIA TREATED WITH SCARLET FEVER SERUM.

BY

ROBERT E. LORD, M.D., B.Sc.LOND.,

CONSULTING PHYSICIAN, COLWYN BAY AND WEST DENBIGHSHIRE HOSPITAL;

AND

JOHN HOLMES, M.B.CAMB., M.R.C.P.,

SOUTHPORT.

THE following case, clinically of septicaemia, is interesting in view of the fact that injection of antiscarlatinal serum seems to have been the deciding factor in bringing about a recovery.

The patient, a boy aged 14¾, was seen on the morning of May 5th, 1929, complaining of pain in the region of his heart, much worse on even slight exertion, such as turning over in bed. The cardiac dullness was increased to 1 inch to the left of the nipple line, and the heart rate was 108, the first sound being impure at the apex. The temperature was normal. The throat was slightly reddened; the tonsils had been efficiently removed some years before. There had been a shiver on the previous night.

There was a history of a feverish attack during the holidays, with sore throat, rapid heart, and a temperature of 101°, for which he had been kept in bed for several days, until he appeared quite well. During this attack there was no suspicion of carditis, though it was looked for repeatedly.

By the next day the patient had a slight rise of temperature, more precordial pain, a blowing systolic murmur limited to the apex, and some pain in his thighs and calves. There was tender swelling of the glands at the angles of his jaws. No rheumatic nodules were felt. Sodium salicylate was given in increasing doses up to 90 grains in twenty-four hours, with sodium bicarbonate.

Between then and May 18th he gradually became worse. His temperature varied between 99° and 101°. He became toxic in appearance; his heart became more dilated and a pericardial rub appeared, as well as broncho-pneumonia in his right lung. No enlargement of liver or spleen and no petechiae or rheumatic nodules were found.

On that day he was seen by Dr. Holmes, and later by Dr. Grace of Chester, who took blood specimens. As the case appeared to be one of septicaemia, probably streptococcal in nature, 10 c.cm. of antiscarlatinal serum were injected intramuscularly.

The pathological report on the blood by Dr. Grace was, briefly, as follows: Widal reactions completely negative to typhoid and to paratyphoid A and B; white cells 12,000 per c.mm. (polymorphs 73 per cent., lymphocytes 18 per cent., mononuclears 5 per cent., mast cells 2 per cent., myelocytes 1 per cent., eosinophils 1 per cent.). After sixty hours' incubation at 37° C. the blood cultures remained sterile.

On May 19th the patient was seen by Dr. Capon of Liverpool in conjunction with Dr. Littler of Southport, who also agreed in the diagnosis of streptococcal septicaemia, and advised a continuance of the serum. The doses of serum from May 18th to May 25th are given below.

Date.	Morning.	Evening.	Remarks.
May 18	—	10 c.cm.	—
,, 19	—	5 c.cm.	—
,, 20	—	20 c.cm.	Temp. 105°; respirations 50.
,, 21	No serum given	—	Some improvement.
,, 22	20 c.cm. + 1 c.cm. sod. nucleinate	10 c.cm.	Suddenly became very ill in early morning; almost moribund
,, 23	20 c.cm. + 1 c.cm. sol. nucleinate	10 c.cm.	Much better in morning and improvement continued.
,, 24	10 c.cm.	10 c.cm.	—
,, 25	10 c.cm. + 1 c.cm. sod. nucleinate	10 c.cm.	—

By this time the boy was definitely much better, his temperature and also his pulse and respiration rates falling, and the physical signs of broncho-pneumonia and pericarditis gradually clearing up. Between May 18th and May 31st he received 175 c.cm. of antiscarlatinal serum, and 25 c.cm. between then and June 10th; his temperature finally settled by June 12th. The only treatment given beyond injection of serum and sodium nucleinate was symptomatic.

The patient was taken home by car, lying down, on July 7th: he then had an appearance of good health, and had surprisingly few physical signs left of the ordeal he had been through. From July 10th to the 13th, however, he had a relapse of a serious nature; he was not as desperately ill as before, and no serum was given.

A blood culture again gave negative results, and a count was as follows: red cells 4,125,000 per c.mm., white cells 9,200 (polymorphs 65.5 per cent., eosinophils 1 per cent., small lymphocytes 22.5 per cent., large lymphocytes 9.5 per cent., large mononuclears 1.5 per cent., basophils 2 per cent.). The temperature returned to normal on July 18th and has remained so, except for a rise to 99°–100° on August 3rd, 4th, and 5th.

On September 11th the physical signs were as follows: temperature 98°, pulse rate 100, respiration rate 18. The boy had a good colour; he had no cyanosis, orthopnoea, clubbing of fingers, or rheumatic nodules. There was visible pulsation in the third and fourth interspaces in the nipple line. The apex beat in the fourth space was half an inch outside the nipple line, and there was no thrill or precordial tenderness. Cardiac dullness extended above to the third rib, on the right to the border of the sternum, and on the left to half an inch to the left of the nipple line at the level of the fourth space. There was a systolic murmur at the apex conducted to the axilla; the pulmonary second sound was accentuated, and a diastolic murmur was heard to the left of the sternum in the third and fourth spaces. The blood pressure on July 9th was 110/60, and on September 11th 138/90. The apex beat moved 1 inch to the left and right when the boy was lying on the corresponding side.

The negative cultures of the blood taken on May 18th, and on a later occasion after his return home, may seem to negative a definite diagnosis of septicæmia, though clinically that diagnosis seemed obvious; and this is made still more likely by the very dramatic improvement on May 23rd, following the injection of 30 c.cm. of serum during the preceding twenty-four hours, which improvement was maintained later until July 10th.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A CASE OF CEREBRAL MALARIA.

CEREBRAL malaria is so rarely seen in England that the following case seems worth reporting.

A gentleman, aged 35, who had recently returned from West Africa, had a rigor, for which he took 10 grains of quinine. Instead of being better the next day he had a very severe headache, and his temperature was still up. He called in a doctor, who prescribed more quinine, without effect. The headache became worse and worse, and vomiting set in. That night he was very delirious, with intense headache and frequent vomiting; morphine gave him no relief. In the morning I was asked to see him as a case of meningitis.

He was then semiconscious, with a temperature of 103.6° F., pulse 112. His head was retracted and could not be moved forward. There was double Kernig's sign, and the toe reflexes were extensor. The abdomen was retracted, the spleen could just be felt below the ribs, and the liver was slightly enlarged. Some of the vomit during the night had been of coffee-ground character.

I came to the conclusion that the case was probably one of cerebral malaria, and asked the doctor to inject 10 grains of quinine hydrobromate into the buttock as soon as possible, and another 10 grains into the other buttock in two hours. In six hours the patient was perfectly conscious and free from headache and vomiting. He was given an intramuscular injection of 10 grains twice a day for the next three days, and had then quite recovered.

This case illustrates the fact that quinine by the mouth is no good in cerebral malaria.

WALTER BROADBENT, M.D.Cantab., F.R.C.P.,
Senior Physician to the Royal Sussex County Hospital, Brighton.

TOXIC EFFECTS OF METHYL CHLORIDE GAS.

IN view of the fact that methyl chloride gas is now used to a large extent in the smaller refrigerating plants, and that medical literature contains no reference to its effects on man, publication of the following two cases would appear to be justified. It must be common for refrigeration engineers to inhale small doses of the gas in the course of their work, and the incapacity that may possibly ensue will give rise to a claim under the Workmen's Compensation Act.

Some experimental work has been carried out in Germany by G. A. Maloff[1] upon the toxicity of some of the chlorine derivatives of methane, as judged by the increase of the fat content of the livers of dogs after exposure to them. Their results show that, while tetrachlor-methane and trichloro-methane (chloroform) show a toxic effect, dichlor-methane, which has fewer chlorine atoms, has no such effect. Unfortunately methyl chloride (monochlor-methane) was not investigated; but it is reasonable to suppose that there is no toxic effect on the liver by this gas, in view of the still fewer chlorine atoms combined with the methyl group.

CASE I.

A man, aged 33, while at work stopping a leak of methyl chloride gas, inhaled a large quantity of it, or assumed that he did, the gas being odourless. He felt faint at the time and vomited, and subsequently suffered from nausea and vomiting of all solid food, and had diarrhœa. Some of the material vomited was dark in colour, but there is no record as to whether this was altered blood or not. His symptoms abated after twelve days, and he returned to light work. His nausea and vomiting were aggravated by a rough crossing to Ireland three weeks after his exposure to the gas, and again on his return to England six weeks after the exposure.

On examination soon after his return he did not look ill. He was somewhat tremulous, and his pulse rate was 112. The thoracic viscera were normal. There was rigidity and tenderness over the epigastrium, and to a less extent over the right iliac fossa. The stomach itself seemed to be tonically contracted, and pressure over the epigastrium made him feel sick. At the time I was not satisfied that his symptoms were due to exposure to methyl chloride, and thought that in any event there was a functional element in the case.

On re-examination six weeks later he felt quite well and had done so for the previous four weeks—that is to say, his symptoms had disappeared two weeks after my first examination, and two months after the exposure. The abdomen was quite normal, and free from tenderness or rigidity. However, he still had a frequent pulse (104), and a slight fine tremor of the fingers and tongue, with brisk knee-jerks, which favoured my previous opinion that he was of a nervous temperament. I was still not satisfied that his incapacity had been due to methyl chloride, but the occurrence of another similar case was regarded as conclusive.

CASE II.

A man, aged 36, on January 18th, 1930, had to disconnect a pipe which he knew to contain methyl chloride, and was exposed to this gas for five hours. At the end of that time he began to feel giddy, vomited, and had diarrhœa. The diarrhœa lasted for one day, but the giddiness and vomiting persisted. His symptoms finally left him after nine days, and at my examination, eleven days after the exposure to the gas, he felt quite well. Neither did my examination reveal any abnormality, either functional or organic. According to his history, this man had had a similar, but slighter, attack resulting from exposure to methyl chloride six months before.

Conclusion.

Methyl chloride gas, after a certain, but unknown, amount has been inhaled, causes giddiness, nausea, vomiting, and diarrhœa of abrupt onset. Recovery takes place after a lapse of time, which varied in the above cases from ten days to two months, and no permanent ill effects have so far been encountered. I am of opinion that the period required for recovery in Case I was prolonged by other factors—namely, sea-sickness and a nervous disposition on the part of the patient. Probably the gastro-intestinal disturbance is of central origin.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

NORTHAMPTONSHIRE DIVISION.

Acute Intestinal Obstruction.

AT a meeting of the Northamptonshire Division, held at the General Hospital, Northampton, on February 12th, Professor D. P. D. WILKIE of Edinburgh gave an address on acute intestinal obstruction.

In the course of his remarks Professor Wilkie said that acute intestinal obstruction was one of the few conditions regarding which there could be no room for differences of opinion as to treatment. Immediate surgical intervention was the only hope, and the high death rate, still of over 30 per cent., was due almost entirely to operation being carried out too late. After referring to the difficulties of the experimental investigation of this subject, owing to the varied and complicated factors involved, he emphasized the important results obtained by experiment in identifying the types of obstruction and the changes in blood chemistry associated with them. It was necessary to distinguish four fundamental types: (1) simple obstruction of the intestinal lumen; (2) closed loop obstruction; (3) interference with the blood supply of the intestine; (4) strangulation. A fifth type—namely, paralytic or adynamic ileus—must also be considered.

In regard to *simple obstruction* the well-known observation that high obstruction was much more rapidly fatal than low was explained by the fact that if a block was established between the upper secretory and the lower absorptive reaches of the intestine a profound disturbance of physiology and blood chemistry occurred, and this was absent in low obstruction until its final stages. The importance of dehydration and loss of chlorides was referred to, and the necessity for generous subcutaneous infusions of normal saline and the intravenous injection of 20 c.cm. of 15 per cent. saline as an integral part of the surgical treatment, was insisted on. Hypertonic saline given intravenously promoted active peristalsis in, and diminished

absorption from, the intestine. Pre-operative and post-operative gastric lavage should be the rule in cases of obstruction, and spinal anaesthesia was the method of choice for operation. Evisceration was to be avoided, and was seldom necessary if collapsed bowel was at once sought for and traced upwards. Opening and draining the intestine was necessary only in cases with marked distension, and then it was usually advisable to leave a valvular tube jejunostomy for some days.

Closed loop obstruction was seen in its purest form in the human subject in the obstructed appendix. It was not yet sufficiently appreciated that the locking up of faecal matter in the *vermiform appendix* by the *impaction* of a concretion in a stenosed area or at a kink led inevitably to gangrene. Experiment had shown conclusively that this was an *inevitable* sequel. It was only by regarding such cases as examples of intestinal obstruction demanding the immediate surgical help which was the accepted treatment for this emergency that we could lower the death rate from the perforated gangrenous appendix—the end-result of such obstruction. Of the 3,000 deaths occurring in this country every year from so-called appendicitis, Professor Wilkie believed that over two-thirds were examples of primary obstruction of the appendix which had been allowed to go on to perforation.

Occlusion of the blood supply to a segment of intestine led to a potential obstruction, but death in such cases resulted from a combination of peritonitis and poisoning from the absorption of autolytic products.

In *strangulation*, the most urgent because the most fatal form of obstruction, there were many factors—obstruction of lumen, closed loop, interference with blood supply, and, lastly, compression or twisting of the mesentery with associated shock. Early operation under spinal anaesthesia offered the best hope of success in these desperate cases. Adynamic ileus was a term which must be used with caution, because it was liable to be confused with true obstruction. Abdominal distension occurring in cases of peritonitis, particularly if associated with colicky pains, was frequently due to a definite organic obstruction of the ileum from plastic adhesions in the pelvis, and for this a jejunostomy was a life-saving operation. For true adynamic ileus, usually found in generalized peritonitis, active surgical intervention could do little, and probably *fomentations, subcutaneous saline, morphine, and possibly* hypertonic intravenous saline and enemata of bile offered most hope of relief.

Reports of Societies.

THE TREATMENT OF URAEMIA.

A MEETING of the Section of Therapeutics and Pharmacology of the Royal Society of Medicine, on February 11th, was devoted to an informal discussion of the treatment of uraemia, Dr. GEORGE GRAHAM occupying the chair.

Professor F. LANGMEAD, introducing the subject, said that, so far as the physician was concerned, uraemia as met with in Bright's disease was a late symptom of an incurable disease. There were different views as to what ought to be included in the term "uraemia," since one school would include all uraemia which could be put down to toxaemia, even renal retinitis, while the other would restrict it to cases with cerebral and gastro-intestinal symptoms, including vomiting and diarrhoea. At present the etiology was shrouded in hypothesis, and it was necessary to unravel the part played by toxins and the part played by supernormal blood pressure and acidaemia. His chief lines of treatment of uraemia consisted of purgation, diaphoresis, and venesection, the last-named being the most important. Care was necessary in prescribing purges for the uraemic patient; the speaker often preferred jalap, since it acted quickly as a cathartic. The evil effect on the kidneys of saline solutions had to be remembered. With diaphoresis he did not hesitate to combine hot packs or radiant heat baths with pilocarpine, if there was no respiratory trouble or heart failure. When twitching and convulsions were present he used morphine. He had seen patients benefit from lumbar puncture, though some physicians objected to it. Diuretics containing mercury were dangerous. In a case of large white kidney, with considerable oedema, 5 per cent. glucose solution resulted in making the patient much brighter, and largely reducing the oedema. Professor Langmead asked whether members had found that giving parathyroid extract and calcium lactate had any effect other than increasing the blood-calcium content. Also, had members employed the system of blood-washing which had been recommended by some Continental authorities—namely, removing 500 c.cm. of blood at a time, and after dialysing it through a collodion membrane (taking care to prevent coagulation) returning it to the circulation? Thyroid extract had been used for diuresis, but since it enhanced the metabolism it did not seem desirable to use it in uraemia.

Dr. E. P. POULTON described a case in which the administration of 15 grams of urea three times a day caused the blood urea to rise to 40 or 50 mg., and the daily urine output to be increased from 500 or 600 c.cm. to 1,500 c.cm. during all the time the urea was continued. It was important to ensure that the amount of albumin lost was made up in the diet taken. He reported various instructive cases.

Dr. W. LANGDON BROWN said the vomit in cases of uraemia contained a large quantity of ammonium salts; he regarded such symptoms as an alternative method of excretion. Skin rashes also indicated such an alternative method, and he had seen them occur in patients with a high blood urea figure. He would include under uraemia three groups: cases with convulsions and amaurosis, those with uraemic asthma, and those with other cerebral manifestations. The first group he attributed to some general toxic condition, in which the kidney might not share, because such symptoms were met with in eclampsia and in the case of the degenerative toxaemic kidney; though dramatic, convulsions were most amenable symptoms. Cases in the third group were associated with a rise of the blood urea content. Uraemia was not due to the urea in the blood: it might be caused by some toxic amino-acid. The speaker did not like using pilocarpine, which, he thought, hastened oedema of the lungs, nor were the newer diuretics containing arsenic and mercury safe in uraemia. In these cases the protein should be cut down at an early stage: fruit juice and sugar were good substitutes for meat. A septic focus often played a very important part in precipitating disaster in uraemic patients. He did not think diarrhoea was wise unless definite oedema was present, since it was a trying process for the heart.

Dr. IZOD BENNETT did not regard the vomiting which was prominent in cases of uraemia as a compensatory or physiological mechanism. He considered that in deaths from uraemia the factor directly responsible for the death was dehydration following excessive vomiting. He had checked vomiting by using barbituric acid preparations, and he had even used morphine for the purpose, since sometimes it seemed to save the life of a patient apparently dying from uraemia. He endorsed the value of venesection in acute cases. Dr. O. LEYTON agreed that the amount of urea in the blood was not necessarily a measure of so-called uraemia. He had seen patients with a high blood urea figure who had no symptoms at the time; there needed to be a very high figure of concentration before urea caused symptoms. Administration of the lactic-acid-forming bacillus was beneficial as regards control of the intestinal flora, but a reliable preparation must be employed. Dr. A. A. OSWEI said that in cases of chronic parenchymatous nephritis with considerable oedema but without much evidence of nitrogen retention, treatment with large doses of alkalis resulted in a satisfactory clearing up of the oedema. All these patients had had symptoms more than a year before the commencement of the treatment. In patients suffering from definite uraemic attacks he had found lumbar puncture extremely useful, and he had never seen harmful effects follow the procedure. Sometimes a patient appeared to have come out of coma because of hypertonic saline injections which had been given; at any rate such patients had been able to live at home for six to nine months before having another attack.

The CHAIRMAN expressed his belief that venesection was very good, but it should, he considered, be restricted to early cases; he had seen patients in late stages who had only 30 to 40 per cent. of haemoglobin, and in them it would be a risky procedure. They stood in more need of blood transfusion, if it was judged wise to give it. When a patient had uraemia it was important to determine the hydrogen-ion concentration of the blood and the patient's reserve of blood. Such tests as he had mentioned occupied considerable time, and so were less often employed than was desirable, but he considered them necessary. Vomiting was apt to increase the alkali reserve. Dr. A. G. PHEAR agreed with Dr. Langdon Brown that pilocarpine was a dangerous drug in these cases, but it was useful when patients were oedematous and needed to have sweating induced. In some instances a hot bath caused the temperature to rise, but there was no sweating, the skin remaining dry and stubborn. The giving of 1/10 or 1/20 grain of pilocarpine to such patients often acted on the heat centre, causing the desired sweating. Lumbar puncture was a valuable proceeding in a limited number of cases, including acute cases with cerebral symptoms, considerable oedema, and convulsions; its effect in reducing the intracranial pressure was chiefly mechanical. Sir WILLIAM WILLCOX emphasized the importance of the physician making sure that he was actually dealing with a case of uraemia, for very similar symptoms were present in cases of advanced morbus cordis, impairment of liver function, and arterio-sclerotic changes in the vessels of the brain. Vapour baths to promote the action of the skin were dangerous in these cases unless the heart was in good condition; he had seen patients die from the effect of them. Elimination by the bowel could be greatly helped by colonic irrigation. Minute doses of morphine could be risked in a case of uraemia if a fair quantity of urine was being passed. For the headache of uraemia large doses of bromides were valuable.

THE RELATION OF NERVOUS SYMPTOMS TO NERVOUS LESIONS.

AT a meeting of the Section of Neurology of the Royal Society of Medicine on February 13th, with Dr. GORDON HOLMES in the chair, a short paper was read by Dr. S. A. KINNIER WILSON on the relation of nervous symptoms to nervous lesions.

Dr. Kinnier Wilson said that at one time he had imagined that clinical conceptions based on clinical differentiations were sufficient for all neurological purposes, but it did not take him long to discover that a purely clinical arrangement was obviously unsatisfactory because a whole group of symptoms of the same kind could arise at different levels in the central nervous system, and as a result of entirely different pathogenic action. It might be thought that epidemic encephalitis was one and indivisible, but its clinical manifestations were innumerable. The clinical-anatomical method had given rise to discoveries and advances of the first importance, but it was rather out of date; it was called, rather contemptuously, the necrological or "mortuary school" of medical thought. He dated his own awakening in the matter largely to the late Sir James Goodhart's paper entitled "The passing of morbid anatomy." Neither clinical nor pathological classification offered any advantage from the standpoint of nosology; the only scientific one would be based on etiology, and further research was necessary. The time had passed when clinical syndromes and pathological complexes could be collated and termed a disease. Some might go as far as Sir Humphry Rolleston and say that there was no such thing as disease, or, rather, that a disease was nothing else than a mental picture, a conception in the mind. At any rate, insuperable difficulties would be found in establishing morbid entities unless it could be proved that a given causative agent produced the same reaction, the same clinical course ensuing, with amenability to the same form of treatment. Physiology knew only three classes of stimuli: those which excited, those which depressed, and those which first excited and then depressed; clinical symptoms should be considered, therefore, as either excitation or depression of function, or as a series in which depression followed excitation. Without exception all were functional. A symptom was the expression of physiological reaction, and thus it could not be specific unless reactions themselves were imagined to be specific, an impossibility when the diversity of agencies and systems was considered. In itself a symptom had no constant relationship to underlying structural relations; a patient with disseminated sclerosis might have ankle clonus one week and not the next. Symptoms *per se* represented dynamic alterations in function, which might or might not coincide with structural change. Further, symptoms themselves, whether due to dynamic or static (structural) change, could not be differentiated. What exactly was expected to be found in a case of neuralgia? It was universally accepted that neuralgia was an extremely prominent neurological symptom, but what alteration was to be found to correlate with neuralgia? The pain must be produced by the stimulation of a normal sensory mechanism, which must be in a state of health, and not of depression. What was expected to be found in a case of tetanus? Recent post-mortem examinations of cases had shown that there was no change at all in the spinal cord cells; that was only to be expected, because in tetanus there was overfunction or release of function of these cells. No constant relationship could hold between the size of a lesion and the amount or mass of functional disturbance. In epilepsy, for example, there was an extreme disorder of function, but with what lesion could it be correlated? Twenty minutes after an epileptic attack the patient was normal. If the cells were then examined nothing abnormal would be found. He did not deny that lesions could be found in epilepsy; he only maintained that there was no correlation between a specific lesion and a specific discharge of function.

The most serious error in the clinical-anatomical method was the omission of the time factor. A few years ago there were many cases of post-encephalitis with inversion of sleep rhythm; but where was this inversion localized? It was not localized anywhere in space, but in time. Since no specificity attached in a general way to nervous symptoms, there arose the homologous question whether pathological changes could be considered specific. His own view was that such changes were reactions to noxious agents. There was a pathological reaction which was common to a number of different conditions, and therefore could not constitute a disease in the scientific sense. The bearing of these problems would not escape the student. They would impress him again with the desirability of regarding disease processes, whether of activity or depression, as indications of vital effort to cope with noxae. Many symptoms were signs of health, and many lesions were attempts at repair.

After a brief discussion Dr. GORDON HOLMES, the president, said that what Dr. Wilson had brought forward was a very close repetition of the teaching of Hughlings Jackson brought up to date. When Hughlings Jackson published most of his work, little was known of modern neuro-pathology, and many of the finer lesions associated with symptoms were not recognized, but his teaching still held good.

Radium and Nervous Tissue.

Dr. E. A. CARMICHAEL brought forward, on behalf of Mr. J. Paterson Ross and himself, an experimental study conducted at St. Bartholomew's Hospital, with a view to ascertaining the effect of radium on cerebral tissue. Radon seeds, with a 5 mm. platinum filter, were placed on the dura mater of rabbits, and the animals were killed at intervals of from three to twenty-four hours. The first thing to occur was a definite change in the staining properties of the cells, followed by congestion of the vessels, fatty degeneration of their endothelium, and finally haemorrhages. In another series of experiments radon seeds, with a 3 mm. platinum filter, were employed, and the animals were killed after periods extending from 62 hours to 60 days. Up to 212 hours, which corresponded to the time of activity of the seed, the size of the lesion was definitely progressive. At the end of 40 days the lesion changed in character, the haemorrhage disappearing and

being replaced by a necrotic area. A further series of experiments, not yet completed, was undertaken with radium needles, which were left in position in the cerebral cortex for long periods. At the end of seven days no effect whatever could be discovered macroscopically or microscopically. Later a lesion appeared, which slightly increased. A point to be noted was that glial tissue actually proliferated under the influence of radium; this raised the question whether it was advisable to use radium in gliomata.

CORONARY THROMBOSIS WITH CARDIAC INFARCTION.

AT a meeting of the Aberdeen Medico-Chirurgical Society on February 6th, with the president, Dr. CHARLES FORBES, in the chair, a demonstration of clinical cases was given. Dr. W. F. CROLL showed a case of coronary thrombosis and cardiac infarction in a man aged 55; the symptoms were as follows.

In September, 1925, the patient began to have what he described as a gasping feeling on negotiating a fairly steep incline, and later pain, definite across the chest, developed, which ceased if he stood still. Under medical advice the patient took things easily, and he was without pain for several months. In December, 1926, while walking more quickly than usual, he was seized with very severe pain in the lower part of the chest and along both arms. The pain over the sternum persisted for a week, in spite of complete rest in bed. On examination the pulse rate was found to be about 120 and regular, the blood pressure 105/60, and the vessel walls normal. The apex beat could not be palpated, the heart sounds were almost inaudible, there were no cardiac murmurs, and no pericardial rub was heard. There were crepitations at the bases of both lungs; the liver and splenic dullnesses were normal, and the Wassermann reaction was negative. The urine contained no albumin. At a later examination in March, 1927, the pulse rate was still fast (101), and the blood pressure 110/20; no apex impulse could be felt. In all areas the first cardiac sound was very faint and the second fairly good. There were no murmurs and the cardiac rhythm was normal. An electro-cardiogram showed inversion of T in leads I and II, a QRS of low voltage, and a left-sided preponderance. At a recent examination, the electro-cardiogram showed increased inversion of the T wave in lead I, an indefinite T in lead II, and an increased voltage of the QRS in all leads. The diagnosis of coronary thrombosis with cardiac infarction was made from the following symptoms and signs: the character of the pain, which was over the lower part of the sternum and adjoining parts of the chest, and radiated to both arms; the long duration of the pain; the persisting rapid pulse; the low blood pressure; the distant cardiac sounds; and the characteristic electro-cardiogram.

Dr. Croll said that the prodromal pain which the patient experienced in 1925 indicated the beginning of the thrombosis, while the attack of severe pain in December, 1926, pointed to complete occlusion of the artery. He showed electro-cardiograms illustrating the characteristic changes which were diagnostic of cardiac infarction, and referred briefly to the prognosis and treatment of this condition.

Treatment of Bronchiectasis.

Dr. R. J. DUTHIE showed a man, aged 31, who was suffering from bronchiectasis. He described the history and treatment, and gave the following clinical details.

The patient said that a tooth had passed down the windpipe in January, 1928; cough and sputum had commenced gradually and had persisted. In November, 1923, he had a moderate haemoptysis followed by severe haemorrhage on three occasions in June, 1929. On admission to hospital in August, 1929, he was coughing up about a cupful of purulent blood-stained sputum every morning. No tubercle bacilli were found after repeated examination, and there was clubbing of the fingers. An x-ray examination showed what appeared to be a foreign body in the left lung; no foreign body could be recognized, however, by bronchoscopic examination on account of bleeding from the left bronchus. A few days later he had repeated copious haemoptyses, and the physical and radiological signs pointed to the bleeding coming from the right lung. This lung was partially collapsed by artificial pneumothorax; since the collapse there had been no further haemoptysis, the sputum was greatly reduced, and the general condition much improved.

Dr. Duthie suggested that the lung collapse should be pushed further by increasing the intrapleural pressure. If pneumothorax successfully stopped cough and expectoration, and if an injection of lipiodol revealed no severe pathological changes in the left lung, permanent collapse of the right lung, either by phrenic erulsion or paravertebral thoracoplasty, might be indicated at some future date.

Other Clinical Cases.

Dr. JOHN CRAIG showed a case of spinal tumour in a girl, aged 10, who had been seen at a previous meeting of the society. In the interval the tumour had been exposed by Mr. A. Mitchell, and diagnosed as an intramedullary glioma, a finding which was confirmed microscopically. It had been impossible to remove the tumour, but the spinal decompression had greatly relieved the symptoms, so that the child could now walk about without support. Deep x-ray therapy was being applied to the growth.

He also showed a long-standing case of melaena neonatorum in a girl, aged 3, who was now in perfect health. When 3 days old she had lost much blood by the bowel and by the mouth. An intramuscular injection of 25 c.cm. of maternal blood into each thigh had an immediate and good effect, the infant remaining well until the age of 2 months, when jaundice appeared. This symptom persisted for two months. Towards the end of the first year the child became very anaemic, although no blood was being lost by the bowel. A blood examination showed 20 per cent. haemoglobin, red cells 2,000,000 per c.mm., and white cells 17,000, of which 10 per cent. were myelocytes. Transfusion of maternal blood by the longitudinal sinus was performed on two occasions, with an interval of three weeks; the child made an uninterrupted recovery and was now a normal healthy girl.

A third case shown by Dr. Craig was of chronic duodenal ulcer in a boy aged 5.

PROGNOSIS AND TREATMENT IN NEPHRITIS.

AT a meeting of the Manchester Medical Society on February 5th, with the president, Professor A. RAMSBOTTOM, in the chair, Dr. H. MORLEY FLETCHER of London gave an address on nephritis, in which he dealt chiefly with prognosis and treatment.

Dr. Morley Fletcher reviewed briefly certain points connected with the structure and functions of the kidney, indicating the channels by which toxins and organisms might reach the kidney—namely, the blood vessels, lymphatics, and ureters. The importance of lymphatic conveyance seemed to have been underestimated until comparatively recently. He called attention to that form of acute nephritis which was associated with severe haematuria, and occurred in children and young adults, being known as acute haemorrhagic nephritis. In this type oedema, if present, was slight, and the urine contained fewer leucocytes than in the ordinary forms of acute nephritis. It usually accompanied acute tonsillitis, also pneumonia and glandular fever, and the prognosis was generally favourable. This condition must be distinguished from simple haemorrhage from the kidney, sometimes called "essential haematuria," and from the form of nephritis which was associated with purpura. The speaker also referred to the rare form of haemorrhagic nephritis of hereditary, familial, and congenital origin which was nearly always associated with deafness, and was probably due to some form of streptococcal infection. As regards the treatment of acute nephritis, stress was laid on the importance of giving, during the first few days, a moderate amount of fluid in the form of water, lemonade, and fruit juice, but no milk, in order to rest the inflamed organ as much as possible. In a few days the diet might be increased by the addition of more fluid and carbohydrates, with fruit and vegetables, but the amount of milk must not exceed half a pint. Further increase of the diet would depend upon the condition of the urine, the amount of oedema, and the results of renal function tests. In discussing chronic nephritis Dr. Morley Fletcher referred to the comparative rarity at present in the large London hospitals of chronic parenchymatous nephritis, or the hydraemic type of renal disease associated with anasarca, as compared with its frequency twenty years ago, and asked whether similar observations had been made in Manchester. The prognosis and treatment of chronic nephritis was dealt with in a consideration of the hydraemic and azotaemic forms. The condition known as nephrosis was described, and recent views with regard to its pathology were discussed. The paper concluded with remarks bearing on the treatment of uraemia.

Reviews.

QUEEN CHARLOTTE'S PRACTICE OF OBSTETRICS.

WE welcome a new edition of the *Queen Charlotte's Practice of Obstetrics*,[1] both because it shows that other hospitals besides the Rotunda in Dublin can write up their practice and make it go, and even more because there is something attractive in the book itself. The very charming frontispiece of its first benefactress, Queen Charlotte, is a cheerful opening, and the homely illustrations of the old Manor House, Lisson Grove, and the original hospital buildings, not only prove that the practice herein set out springs from the pure fountain head, but seems also to give an air of simple domesticity to the book that is disarming to criticism. These old institutions have their traditions, and the family touch has been well maintained, though the band of brothers in authorship have not confined themselves too strictly to Queen Charlotte's practice. They decided to make a textbook, and to make it complete by including the scientific foundations of obstetrics as well as its practice, and, from their own wider experience, have filled in the blanks in the hospital's experience by considering fully abortion, ectopic pregnancy, and other conditions that do not usually fall within the sphere of a lying-in hospital.

The features of the book can be best illustrated by picking out a few samples here and there, and a start may be made with occipito-posterior positions—one of the bugbears of midwifery practice. These positions are said to form 45 per cent. of the vertex cases examined in the ante-natal clinic, but in all except 2 per cent. delivery took place with the occiput anterior, and even among this 2 per cent. only a small proportion gave rise to difficulty. These figures are somewhat surprising, and raise a doubt as to the reliance to be placed on abdominal diagnosis at the thirty-sixth week of pregnancy. Otherwise they are a remarkable tribute to the powers of nature—if given a proper chance. The signs differentiating favourable from unfavourable cases and the management of difficult ones are clearly set out—the hospital practice at Queen Charlotte's following generally accepted lines. The authors have not a good word to say for abdominal prophylactic manœuvres by pad and binder.

The chapter on contracted pelvis is excellent, particularly the discussion of the place of induction of labour, trial labour, and Caesarean section. The time of election for induction is not the time when the head will just enter the brim, but the later date when it just will not. In a trial labour rupture of the membranes is the event which determines the need for full investigation of the conditions present. If prolapse of the cord is discovered Caesarean section is performed at once, otherwise a decision is reached on the strength of the contractions and the progress made in six hours or so. Further waiting is justified by fixation of the head and descent, even if slow. If forceps delivery fails perforation is preferred because of the lesser risk to the mother and possible cranial trauma of the foetus.

No complaint can be made of lack of emphasis regarding the treatment of placenta praevia: "Too much stress cannot be laid on the dangers of rapid delivery." There is a very instructive analysis of Caesarean section, the classical operation being considered almost exclusively. The final conclusion is that in clean operations alone the risk is at least three times that of a normal labour. The final chapters include a strictly domestic account of the vaccination of young infants as practised at the hospital, and a general review of maternal and foetal mortality in the country, their causes and prevention.

The book is one of which Queen Charlotte's Hospital may well be proud: it is full of sound practical common sense, and has an individuality, rarely found in composite works, that succeeds in conveying something of the hospital atmosphere and tradition. We wish it the long and continued success it merits.

BONE AND JOINT SURGERY.

IN a preface to his book on the active surgery of the limbs[2] Professor LECÈNE, whose recent death will be generally deplored, disclaimed any attempt to deal with operative surgery on the dead body, valuable as he holds such practice to be for the student. As his publishers say, his work, while not a treatise on the pathology of the limbs, is something more than a manual of operative surgery, for in it the indications for the different procedures and their results are discussed with some fullness. The author himself insists on the great importance of a practical knowledge of applied anatomy, without which the operator may easily find himself in difficulties. Questions of etiology, pathology, prognosis, and the relative value of different procedures occupy a secondary place; the author's main object seems to be to describe the operative measures that he himself has found most useful, and in this he has succeeded. The first part deals with open methods of treating fractures and pseudarthroses, the second with osteomyelitis, the third with tumours and dystrophy of bones, and the fourth with wounds of joints, dislocations, and ankylosis. Several chapters are devoted to surgical tuberculosis and the technique of amputations and resections, and finally the surgical treatment of skeletal deformities is dealt with.

The title of the book might lead the reader to suppose that it includes the greater part of orthopaedic surgery of the limbs, but a further acquaintance with its contents, despite its bulk and wealth of illustrations, will show that it is as an operator that Professor Lecène envisages his subject, and not as an orthopaedist to whom an operation is merely an incident in the course of restoration of function. An example of this is found in the article on congenital luxation of the hip, in which the author dismisses the subject of bloodless treatment in half a dozen lines, but goes on to describe and illustrate an operation of osteotomy and factitious pseudarthrosis in cases too old for reduction. The use of splints is ignored throughout, and nearly all of the 337 figures represent procedures on the operation table with chisel or knife or metallic plates. Professor Lecène has very little to say about arthroplasty, and ignores the work of American surgeons on this subject. The illustrations are excellent, and within its limits the book should be useful as a guide to operations on the skeleton.

PSYCHOPATHOLOGY.

A BOOKLET by Dr. R. D. GILLESPIE on *Hypochondria*[3] will be read with interest and advantage by both the general medical practitioner and the psychiatrist. The malady with which this compact and engagingly written essay is concerned is discussed from its historical, clinical, and psychopathological aspects. The author considers that the hypochondriacal reaction type can, and should, be clinically differentiated from hysterical and anxiety cases with hypochondriacal symptoms. The clinical criteria for regarding a condition as essentially hypochondriacal are stated to be as follows: a mental preoccupation with a real or suppositious physical or mental disorder; a discrepancy between the degree of preoccupation and the grounds for it, so that the former is far in excess of what is justified; and an affective condition best characterized as interest with conviction and consequent concern, and with indifference to the opinion of those around, including irresponsiveness to persuasion. It is clearly desirable on practical grounds that this reaction type should be distinguished from others which it may in some ways resemble, for, unlike these, it is singularly refractory to psychotherapy, and the prognosis is unfavourable. In the concluding chapter Dr. Gillespie discusses what he calls *hypochondria epidemica*—a tendency to morbid preoccupation on the part of the press and populace in regard to health matters, cures, and diets. It may well be, as the author suggests, that an

[3] *Hypochondria.* By R. D. Gillespie, M.D., M.R.C.P. Psyche Miniatures, Medical Series. London: Kegan Paul, Trench, Trubner and Co., Ltd. 1929. (Pott 8vo, pp. 107. 2s. 6d. net.)

increasing doubt of the perpetuation of individual existence after bodily death unconsciously or consciously influences people to cling more closely to the present life.

A volume entitled *The Case of Miss R.*[4] is the translation into English of an interesting study by Dr. ALFRED ADLER. The author has taken the life story of a girl of ordinary station and no particular accomplishments, and submitted it to a psychological analysis. This self-revealing story, written by the girl herself, was dealt with by Dr. Adler in a manner similar to that which he would have adopted in listening to the psychological history of a patient in his consulting room. Each sentence or paragraph was examined from the beginning, without any knowledge of the story as a whole, and running comments made upon its psychological significance. By proceeding in this manner the author was able to give a picture of the procedure followed in an analytical investigation, and to show how a psychopathologist armed with a store of experience listens to, apprehends, works over, and understands an ordinary and otherwise insignificant life story. Briefly, this book is intended to show, by reference to a concrete case, how an analysis carried out on Adlerian lines is conducted, and the kind of deductions to be made from the study of apparently insignificant self-revelations. Dr. Adler states that he has never seen the girl whose story he has studied, but has heard that, in so far as she has been able to help herself without the aid of a psychologist, she has freed herself from the compulsion neurosis from which she suffered, and is taking courageous steps to solve her difficult life problems. It is left to the imagination of the readers of this volume, to their psychological understanding and intuition, to divine how this happy outcome was achieved. Dr. FRIEDRICH JENSEN, the editor of this translation, writes a preface in which the Adlerian conception of the nature of a neurosis is concisely outlined.

Those who wish to acquaint themselves with the principles and practice of Adlerian teaching can scarcely do better than consult a volume on *Individual Psychology*[5] by Dr. ERWIN WEXBERG. The translation into English of a smaller work by this writer on the same subject was recently reviewed in these columns. Dr. Wexberg is peculiarly fitted to undertake the task of writing this systematic work, for he has been associated with Dr. Adler as a co-worker in Vienna for some years. The general practitioner will no doubt find the psychotherapeutic method here described to be one of practical value in dealing with psychoneurotic cases and problem children. The technique of this method differs considerably from that of psycho-analysis. Apart from the therapeutic aspect of individual psychology, reference is made to the pedagogic and cultural aspects of Adlerian teaching. How far a more general understanding of the principles expounded in this work is calculated to exert a beneficial effect upon society generally we cannot pretend to estimate, but it may certainly be said that there is much in Adlerian teaching which those who are concerned in the upbringing and education of the young will find definitely helpful.

PATHOGENIC STREPTOCOCCI.

THE fifth volume of the *Annals of the Pickett-Thomson Research Laboratory*[6] is devoted to three monographs, forming part of what the authors—Drs. D. and R. THOMSON—justly describe as a gigantic work on the streptococci. They have already published two ponderous volumes, one of which we reviewed on August 3rd, 1929 (p. 206), a fourth is in course of preparation, and a fifth, consisting of an atlas of photographs, will bring this encyclopaedic work to a conclusion.

The research is to a large extent morphological, and depends on the employment of the special culture medium prepared by Warren Crowe, although the varying action of the cocci on the blood colouring-matter of the medium is also made use of as heretofore. The medium, the preparation of which has been described by Warren Crowe in the *Journal of Pathology and Bacteriology* (1921, vol. xxiv), appears to owe its properties partly to its smooth and equable surface, which permits of the natural growth of the colonies, free from accidental irregularities. Enlarged photographs of the colonies bring out essential details of form and enable constant variations to be distinctly recognized; and the study of these has led the authors to conclude that a great number of distinct subspecies of streptococci exist, which have hitherto escaped detection. There appears to be no *a priori* reason why microbial flora should exhibit less diversity of form than ordinary flora, but it has been objected that the differences stressed by the authors may be merely such as, in the case of elm trees for example, distinguish individuals. The colonies figured in the authors' plates exhibit abundant individual differences of this kind; on the other hand, they bring out resemblances which are clearly indicative of natural groups. For example, points of resemblance in certain of the colonies in a mixed culture enable the presence of the well-defined form of *Streptococcus mutans* to be recognized without difficulty. Whether all the groups distinguished by the authors are natural groups experience alone can show; meanwhile, the authors must be credited with affording a much more intimate acquaintance with the streptococci than has been possible hitherto, and one that is likely to be of practical consequence.

The general plan of the authors has been to study the several regions of the body in succession, in the first place as regards the normal bacterial flora, and secondly in various diseased conditions. Thus in the case of the mouth the normal incidence of streptococci is first described, and then the bacteriology of streptococcal glossitis and stomatitis, dental caries, and pyorrhoea alveolaris, an attempt being made to identify, among the numerous forms, the individual organism causing the disease in each case. The account is accompanied by an analysis of the very extensive literature of the subject and a discussion of the views of the numerous authors cited. The present volume deals with the role of streptococci in oral and dental sepsis, tonsillitis and pharyngitis, and in puerperal sepsis and septic abortion. The plates are excellent and enable the reader to form his own opinion as to the validity of the authors' conclusions.

NURSERY CRAFT.

DR. LESLIE HOUSDEN has added another to the many books on this particular subject, but for once the publisher's claim that his *Mothercraft*[7] is different is justifiable. Wittily written in clear simple language, this small volume contains a great deal of sound common sense for the expectant and nursing mother. Chapters on preparation for the baby, breast-feeding, weaning, baby's health, the training of children, and clothing comprise the whole contents, from which it will be seen that all account of artificial feeding is deliberately excluded. The author is never dogmatic without giving his reasons, his illustrations are always apt, and he ruthlessly deals with all fads and cranks. This is certainly a book for well-meaning friends and "expectant grandmothers" to read, for the modern mother suffers less from ignorance than from the prejudices of those around her.

During the twenty-two years which have elapsed since Dr. ROBERT S. MCCOMBS first published his *Diseases of Children for Nurses*[8] much advance has been made in the subject of paediatrics, and constant revision of the book has been necessary. The sixth edition, just issued, contains new articles on pre-natal care, blood chemistry, and vitamins, while the articles on nursing have been enlarged and revised so that the volume now contains an account of the nursing

[8] *Diseases of Children for Nurses.* By Robert S. McCombs, M.D. Sixth edition, thoroughly revised. Philadelphia and London: W. B. Saunders Company. 1929. (5½ × 8, pp. 583; 137 figures. 12s. 6d. net.)

as well as of the diseases of sick children. The surgical side is for the most part neglected, and this seems an important omission in a book for nurses, who should have no rigid division in their minds between medical and surgical cases. Details about the nursing and after-care of children who have had tonsillectomy, the commonest surgical operation, are not given; nor is sufficient mention made of acute abdominal conditions and their nursing. What Dr. McCombs has included, however, is presented clearly and in a manner well adapted to those for whom the work is intended.

"BURDETT."

Burdett's Hospitals and Charities[9] is a publication which is now in its fortieth year of existence. It remains a very useful and complete compendium of charitable work in this country. In the preface attention is directed to new forms or schemes for co-ordination that have been devised, with a reference to the "incalculable reactions" which the staffing problem of municipal hospitals under the new Local Government Act may lead to. Among new institutions which have come into being, mention is made of the Marie Curie Hospital at Hampstead, for the radium treatment of cancer in women; of the Lord Pontypridd Hospital in Wales, for early rheumatic heart cases in children; of the opening by the managers of the Royal Edinburgh Hospital of the Jordanburn Nerve Hospital, for the voluntary treatment of mental disease; and of the establishment of a "foot hospital" in Liverpool. The astonishing vitality of the Hospital Saving Association in London is noted. In a brief survey of the voluntary hospitals and their problems, Captain J. G. Stone comments on the scheme for medical centres now being developed in Birmingham, to which reference was made in the *Journal* of February 8th (p. 255). He touches upon the hardships inflicted upon some hospitals under the Rating and Valuation Act, 1925; and on the expense involved in the treatment of motor accident cases. He sets forth the figures which show that the total income of voluntary hospitals now amounts to £14,000,000, of which over £12,000,000 is derived from various voluntary sources; and that a net aggregate deficit of more than £600,000 in 1920 has now been turned into a net aggregate surplus of nearly £1,000,000. The information given in the volume seems to be reasonably correct in view of the enormous labour that must have been involved in its compilation. It is perhaps a pity that a public school such as Epsom College should be compelled by its close charitable connexions to appear in the book, while other public schools, some of them with similar, though less closely connected, charitable objects, are unnoticed.

NOTES ON BOOKS.

DR. J. R. REES, in *The Health of the Mind*,[10] propounds the need for sound principles of mental hygiene in the early life of the child. "The mental hygiene movement," he says, "is going far towards ensuring a better balance and poise in the next generation." "Individually and collectively we suffer to an extent which few appreciate, because of ignorance of the ordinary principles of mental hygiene." Dr. Rees is deputy director of the Tavistock Square Clinic, London, and the scope of his little book, which does not set up to be in any sense a technical work, may be sufficiently indicated by giving a list of the chapter headings. These are, in order: mental health; bodily mechanisms; instincts and the personality; mind and body; psychological mechanisms; mental breakdown, its cause and its cure; the problems of early life; the problems of childhood and adolescence; adult problems; sex education; the art of adjustment.

The second edition of CAMERON'S *Textbook of Biochemistry*[11] has fully maintained the high standard set by its predecessor, which appeared as recently as 1928. There is no need to repeat what we had to say in its praise at that time, though we believe it was fully justified. To criticize a book of this type is so much easier than to write one that we feel some hesitation in pointing out what appear to us to be omissions: but we cannot help thinking that the work of Mann and his collaborators, which has done so much to clarify our views on liver function, might well have been dealt with rather fully. The chapter on pharmacology, too, is not quite up to the standard of the rest of the book; we think that the author would have done better to treat the matter more adequately, or else leave it out altogether.

Under an arresting title, *Those Teeth of Yours*,[12] and with the subtitle "A popular guide to better teeth," Mr. MENZIES CAMPBELL makes a serious endeavour to awaken the public's interest in the preservation of their teeth. The first chapter, with its brief history of dentistry from remote times to the present day, provides a fitting prelude; and the last chapter—on the claims of dentistry as a career, reminding both the general public and the dentist that social service is the goal of the dentist as of the doctor—is an epilogue of equal fitness. The anatomy of the teeth, the causes of decay, pyorrhoea alveolaris, extraction and replacement of teeth, children's teeth, teeth in relation to health, are dealt with in the intervening chapters. As a general criticism we may say that the author presents as settled fact debatable points on which professional opinion is by no means unanimous. Not everyone will agree that the withdrawal by the body of lime salts from the teeth to fulfil its other needs is the explanation of the first stage of enamel caries (p. 42), or that iron injures the teeth (p. 47). Nor would everyone agree that extraction of the first permanent molar teeth produces such terrible results as are depicted in Fig. 13 (to us it seems that the two jaws there depicted belong to two separate persons, and so are not comparable). But, withal, there is much that will interest the general reader and much that will stimulate inquiry, and the author's style makes pleasant reading. We hope that the book will arouse the interest in a difficult subject which the author desires.

PREPARATIONS AND APPLIANCES.

A BED FOOT-REST.

DR. H. F. EALAND (Farnham) writes: A simple apparatus which will enable the patient to be kept in the sitting position while in bed has long been wanted. Up to the present the only means of doing this has been by using the ordinary "donkey," but this has disadvantages which are apparent to everyone.

The apparatus here illustrated has many advantages; it is simple, easily adjustable, comfortable, and inexpensive. It

consists of two slats of wood, one of which is placed under the iron frame of the bedstead, and the other, to which the foot-piece is fixed, is placed over the mattress. These two slats are clamped at each end with simple screw clamps. A pillow is then folded over the foot-piece.

This bed foot-rest is supplied by Messrs. Allen and Hanburys Ltd., Wigmore Street, W.1.

INVERT SUGAR.

Sunnycomb is a pure invert sugar prepared from cane sugar by Macfie and Sons, Ltd. (34, Moorfields, Liverpool). It resembles honey in appearance and sweetness, and is a very palatable preparation. It is therefore a convenient substitute for sucrose in cases where such a substitute is required.

CHOCOLATE MILK FOOD.

Cow and Gate chocolate milk food is a blend of cocoa, full-cream milk, and cane sugar. It is sold in powder form, and from this a palatable drink can be prepared simply by the addition of hot water. It is specially recommended for convalescents, etc., who dislike the taste of ordinary milk.

THE PATHOLOGY OF BONE.

IT might be supposed that the seventy-five Hunterian orators who have preceded Mr. Hey Groves in that capacity can have left very little of interest unsaid in connexion with the life and work of John Hunter. Yet Mr. Hey Groves (whose oration is printed at page 321) has succeeded in breaking new ground. He has approached the subject from a Carlylean standpoint, and in his study of the hero as surgeon or surgeon-biologist, with John Hunter as type and representative, has found material for a discourse which, in point of freshness of interest and eloquence, will surely rank high in the series of Hunterian orations. The adoption of this standpoint will be felt to be singularly appropriate; for it implies the recognition of a certain degree of idealism, and there can be no doubt that a halo surrounds the memory of John Hunter such as may be found about that of few other scientific men. We know, indeed, how to appreciate Hunter's work, but with the mention of his work we never fail also to recall his personality and himself. This hold on our sentiment is no less evident in the manner in which the great collection which he has bequeathed to us is regarded; every specimen of that collection, be it of great or of little intrinsic worth, is looked upon with an almost mediaeval reverence because it belonged to him. It is possible that the frank sincerity of the man, which Mr. Hey Groves mentions as being one of his main characteristics, may in some measure account for the affection in which his memory is held.

Hunter was especially interested in the pathology of the skeleton, and this year's oration is chiefly devoted to the consideration of this aspect of his work, and more particularly to bone-grafting, in which Hunter may be said to have been a pioneer. Hunter's experimental graft of a hen's spur into the leg of a cock is considered to be the first successful example of bone-grafting on record, and by it the fundamental fact was established that the organic union of an implanted bone with the tissues of the host is a possibility. The subsequent history of this branch of surgery forms an interesting chapter, to which Mr. Hey Groves himself, in his Jacksonian prize essay of 1916, has been a notable contributor. Following Hunter, no considerable progress was made until the middle of the last century, when Ollier of Lyons, who may be regarded as the second founder of the method, took up the study of the subject from a biological standpoint. Ollier believed—and it was the general belief at the time—that the periosteum took no part in the production of bone; but he was forced from that position by the results of his own experiments. For he found that when the periosteum was reflected away from the shaft of a bone a new production of bone did occur on its deep surface. He was thus led to believe that the periosteum not only possessed an osteogenetic function, but that it was of primary importance in ensuring the viability of a transplant and in producing the bulk of the ultimate graft. This preponderating influence of the periosteum was questioned by Barth in 1893. His observations pointed to the complete death of the transplanted bone; and he conceived that the definitive graft arose by a production of new bone from the cut extremities of the diaphysis of the host. Hence arose the idea of the original transplant acting merely as a scaffold of dead bone, to be gradually replaced by osteogenetic tissue permeating it from the surrounding parts, macroscopical evidence of which is seen in the gradual rarefaction of the osseous tissue of the original transplant.

Barth's views received some modification through Axhausen's work in 1908, by which it was shown that, although the main part of the transplant dies, some degree of endosteal and subperiosteal bone formation may be retained. The fact of the permeation of the transplant appears, however, to have been now established without doubt by Leriche and other observers. At this stage, then, ideas on bone-grafting had taken definite form; the fate of the original transplant was understood, and the relative parts played by the periosteum of the transplant and the osteogenetic tissue of the host were satisfactorily apportioned. In 1912, however, Macewen published his work on the growth of bone, and the whole theory of bone-grafting seemed to be returned to the melting-pot. Macewen repeated Ollier's experiments, employing a more exact technique, by which, in raising the periosteal flaps, he avoided the inclusion of any of the subjacent bone, as it became evident had happened in Ollier's experiments. These experiments appear to prove that the periosteum has no osteogenetic function whatever, and on Macewen's authority that view has been generally accepted, the periosteum being regarded merely as a vascular limiting membrane, but useful as such in assisting in the organic union of the transplant. Without mentioning Barth by name, Macewen appears also, in the following passage, to dissent from his conclusions. "It has," he writes, "been alleged that transplants do not live and grow, that they merely play a passive role, and that a new growth does take place into them from either side of the diaphysis." He then describes experiments with minute fragments and shavings of bone which, when transplanted, he considered to survive and act as centres of ossification. These experiments can hardly be regarded as touching Barth's position, which was concerned with transplants of no little bulk; and, as a practical proposition, it is still held that the main part of the transplant dies.

With the acceptance of this view it seemed but a natural corollary to assume that dead bone would be as efficient as a living transplant—an assumption which receives its justification in an interesting experiment described in the Jacksonian essay above referred to, in which two grafts, one of living and the other of dead bone, in the shape of pegs, were fixed in the living bone of the host, and were found at the end of a few weeks to exhibit no recognizable differences, macroscopically or microscopically. An essential condition for success in these operations, in order to ensure satisfactory permeation of the transplant, is that the latter should be firmly fixed in close contact with the living bone of the host, ample demonstration of which has been furnished by Mr. Hey Groves himself. Permeation, however, is not a necessary consequence in every case, and bone, if of very dense texture, may become encapsuled after the manner of an aseptic foreign body, and its presence be tolerated. A remarkable example of this is alluded to by Mr. Hey Groves in a case in which he inserted the tooth

of a walrus into the centre of a boy's femur, the tooth becoming firmly and permanently encapsuled in osseous tissue, without permeation.

Mention has been made of Macewen's experiments with small transplants of bone. He supposed that these increased in size through an abundant proliferation and outpouring of osteoblasts. Recently our ideas of osteogenesis have been again disturbed by the emphatic assertion of Leriche and Policard that osteoblasts have nothing whatever to do with bone formation—that they are rather a hindrance than a help to that process. We thus appear to be at the opening of a new chapter in the pathology of bone; and we may anticipate that new facts and new theories will be forthcoming, which will doubtless furnish new material for the successors of Mr. Hey Groves on the Hunterian rostrum.

HEALTH SERVICES AND THE QUALIFICATIONS OF MEDICAL OFFICERS.

ONE of the objects of the late Government and of Parliament in passing the Local Government Act of last year was to effect a greater freedom for local authorities from central departmental control over the detailed expenditure of public money. Under the system of "grants in aid" covering a high proportion of the total expenditure involved, there was a logical case for meticulous interference on the part of the Ministry making the grant; on the "block grant" system Ministerial control may become of a much looser and more general character. Indeed, the danger is that in the case of backward and unwilling authorities this control may be too remote to be really effective. These observations apply, of course, to the public health services—perhaps predominantly to them. In pursuance of the policy of allowing as much freedom as possible to local authorities in administering those services, the Ministry of Health has just issued a circular (No. 1072) and accompanying regulations laying down some general requirements as to the qualifications which must be possessed by those who are hereafter appointed as medical officers or health visitors in connexion with tuberculosis, venereal disease, and maternity and child welfare services, and stating the general conditions under which laboratories and institutions connected with these services will be approved. These documents are of great importance, since their effect is that after March 31st next it will no longer be necessary for local authorities to obtain the approval of the Minister of Health to individual appointments of any of the officers concerned provided the regulations are complied with, and that, subject to the conditions stated, sanction is given in advance to any developments of these health services (in cases where approved schemes are already in operation) to any extent and in any manner that the local authority thinks desirable—so long as such developments do not involve the raising of a loan to defray any necessary capital expenditure. The sanction of the Minister will still be required, of course, for the initiation of arrangements in local government areas where no scheme has hitherto been sanctioned.

The medical officers concerned with these regulations are (1) a "tuberculosis officer" in clinical charge of a tuberculosis dispensary provided by a local authority; (2) a "medical superintendent" in clinical charge of a residential institution for the treatment of tuberculosis in its early or curative stages which contains not fewer than seventy-five beds; (3) a "venereal diseases pathologist" in charge of a laboratory, and (4) a "venereal diseases officer" in charge of a treatment centre provided by a local authority; (5) a "senior maternity and child welfare officer," other than a medical officer of health, in charge of the maternity and child welfare work of a local authority, who has responsibility for the work of other medical officers similarly employed; and (6) a "medical officer of an ante-natal clinic" in charge of a clinic provided by a local authority for giving advice to pregnant women. The first requirement in respect of all these officers is that they shall have had at least three years' experience in the practice of their profession subsequent to qualification. It will be remembered that such a requirement was originally suggested by the British Medical Association in connexion with the establishment of a scale of salaries for the public health medical service. This requirement is now officially adopted. In the case of the first two of the above classes of medical officer there are further requirements: that they shall have spent not less than eighteen months in general clinical work, including six months as resident officer in charge of beds in a general hospital, and that they shall have received not less than six months' special training in the diagnosis and treatment of tuberculosis. This will do something, though perhaps not enough, to improve the status and usefulness of tuberculosis officers. In the case of the venereal diseases officers, the pathologist is required to be properly certified as having done a specified amount of laboratory work of a special kind, and the clinical officer must be "in possession of a certificate given by the venereal diseases officer of a treatment centre at which not less than five hundred patients attended for the first time during the twelve months preceding the issue of the certificate, testifying that he has attended at the treatment centre for not less than three months, and has received during that period not less than one hundred and thirty hours' instruction in the modern methods of diagnosis and treatment of venereal diseases." A committee of the British Medical Association suggested to the Minister of Health that the requirement as to 500 new patients having attended the centre in a year was too stringent, but was assured by him that there would in fact be no difficulty in finding a number of such centres sufficient for the purpose required. The senior maternity and child welfare medical officer is required to have been employed as a junior officer in this department of work, and both he and the ante-natal clinic officer must have had special experience, with this curious difference, that such experience must have been in the case of the former officer "in midwifery," and in the case of the latter officer "of practical midwifery." The necessary qualifications of health visitors and of tuberculosis visitors are similarly set out.

With regard to the approval of institutions, the only conditions required to be observed are (1) that the institution and the records kept thereat will be open to inspection at any time to officers of the Ministry of Health; and (2) that such records be kept and returns made as the Minister may from time to time require. Further, institutions for children must make such arrangements for their education as the Board of Education may require; and in laboratories the Wassermann tests must be performed under the personal supervision of the medical officer in charge of the laboratory, and must conform to a standard technique. Lastly, authorities are reminded that inspections will be carried out in connexion with all these services to see that a reasonable standard of efficiency and progress is maintained.

THE HUNTERIAN FESTIVAL.

THE Hunterian Festival of the Royal College of Surgeons of England was held last week on the two hundred and second anniversary of John Hunter's birth, when Mr. Ernest W. Hey Groves, professor of surgery in the University of Bristol, delivered the Hunterian Oration, which is published in the opening pages of this issue. In the evening a dinner was given in the College Library, where a large company was entertained by the President and Council. After the usual loyal toasts had been honoured, and "The Memory of John Hunter" had been drunk in silence, the health of "The Guests" was proposed by the President. In the course of his eloquent and witty speech, Lord Moynihan paid compliments to a number of the distinguished visitors, including the Dean of Westminster, as representative of the Church; Lord Atkin, Mr. Justice Hawke, and the Treasurer of Lincoln's Inn; the King's physicians, Lord Dawson, Sir Humphry Rolleston, and Sir Farquhar Buzzard; and Mr. Arthur Greenwood, Minister of Health, whom he delighted to welcome as a fellow-citizen of Leeds. Lord Moynihan said that Mr. Greenwood was holding office at an extremely interesting period in the history of medicine, because he had the opportunity to create the long-hoped-for post-graduate medical centre in London beside which Vienna and Berlin would pale into insignificance. The Minister of Health, in an appreciative reply, said that he had been much impressed by the President's inspiring appeal on behalf of post-graduate medical education and research in the capital of the British Empire; it was an ideal to quicken even an untutored layman's mind. Lord Atkin, who also responded, discussed some of the resemblances and contrasts between law and medicine upon which the President had lightly touched, and urged the Minister of Health, when considering plans for a great post-graduate centre, to bear in mind the need of a medico-legal institute in London where magistrates, coroners, counsel, police surgeons, and others could be trained in the principles and methods of medical jurisprudence. The concluding toast, that of "The Hunterian Orator," was given by Dr. Thomas Loveday, Vice-Chancellor of the University of Bristol, who spoke with enthusiasm of the pride felt by his city in the honour that had been paid that day to Professor Hey Groves.

TULARAEMIA.

PLAGUE, one of the most important and widespread of the great epidemic diseases, owes much of its importance to the fact that it is primarily a disease of rodents. But it is not the only disease of rodents which is transmissible to man. Another plague-like condition—tularaemia—first observed in 1907, though not then identified, is conveyed from rodents to human beings with the greatest facility. Named after the county of Tulare in the United States, where the causal organism was first isolated, it infects a large variety of rodents (as well as many different species of wild and domestic mammals and even birds), producing plague-like symptoms, such as buboes and so forth. Unlike plague, however, the disease is relatively benign in human beings, though it has a high mortality among animals. Tularaemia was first officially recognized in the United States in 1912, but was comparatively unknown even as recently as 1928. Apart from a few cases recorded from Japan, it appeared to be limited to America: since 1926, however, a number of epidemics in the Union of Soviet Socialist Republics—occurring on both sides of the Ural Mountains, and extending from the Arctic Circle to the Caspian Sea—have shown that the disease is much more widespread than had been thought.[1] There is a good deal of evidence, too, to suggest that it is not a new disease and that many of the benign epidemics of "plague" were really tularaemia. Derbek recorded, for example, an epidemic in 1877, in Astrakan, which was almost certainly of this condition. Clinicians in the United States have so far recognized four more or less distinct forms of tularaemia: ulcero-glandular, oculo-glandular, pure glandular, and—found mainly among workers who have contracted the disease in the laboratory—typhoid; but the Russian investigations have shown that this classification is inadequate and requires revision. The causal micro-organism, *B. tularense*, shows certain serological relationships with the micro-organisms of undulant fever and contagious bovine abortion, but these are not sufficiently distinct to warrant its inclusion in the same group. Indeed, it appears to be much more closely related to Yersin's bacillus than to any other: but serologically much still remains unknown, and there appears to be no cross-immunity between the two micro-organisms. Tularaemia, though bacteriaemic, is not transmitted directly from animal to animal or from man to man, but through the bite of an insect or a tick, or through actual contamination of broken skin or conjunctiva. This peculiarity makes it almost an occupational disease, fur hunters, and to a less extent laboratory workers, being the chief victims. The recent widespread epidemics in Russia arose mainly through the demand for the skins of water-rats—animals which are not normally hunted to any great degree, but whose skins have suddenly become valuable because of the world demand for furs of any and every description—and in this way hundreds of hunters and fur skinners have become infected. Plague, too, may arise very occasionally as an occupational disease among fur hunters: as, for example, it did in Mongolia, where the hunting of tarabagan originated outbreaks. Research has shown that in many places in the U.S.S.R., even where human epidemics have not been reported, the disease is endemic in rodents, and tularaemia therefore assumes a real public health significance. Russian workers are displaying great activity in many branches of biological research—very much greater than is generally realized; indeed, in some of its branches they are far more active than workers in our own country. In this particular instance extensive epidemiological studies on tularaemia are in progress, and their results cannot fail to be of the greatest interest to public health authorities throughout Europe.

[1] Monthly Epidemiological Report of the Health Section of the Secretariat of the League of Nations. Ninth year, No. 1. Pp. 2-21.

THE INVESTIGATION OF NEW DRUGS.

THE introduction of new synthetic drugs has been an outstanding feature in the progress of therapeutics during the present century. Discoveries of the highest value have been made in this field, but still it must be admitted that the rate of advance in drug therapy lags behind that made in other comparable fields. The rapid development of gas warfare during the war is an indication of what can be done by systematic team work on a large scale. There is certainly a striking contrast between the speed with which noxious gases of ever-increasing potency were discovered and the slow advance in our knowledge about healing drugs; the contrast does not reflect credit on humanity. An interesting discussion at the Annual Meeting last July of the American Medical Association[1] brought out some of the causes for the unsatisfactory rate of progress in the discovery of new drugs. The problem is threefold—chemical, pharmacological, and clinical. When a new drug is produced in the chemical laboratory its properties ought first to be subjected to pharmacological analysis, and it should then be tested clinically. The difficult problem is how to organize disinterested tests. The pharmacological assay is important because, as Dr. C. D. Leake observed in his opening paper, "there is no short cut from chemical

[1] The Pharmacologic Evaluation of New Drugs. *Journ. Amer. Med. Assoc.*, 1929, 93, 1521.

laboratory to clinic, except one that passes too close to the morgue." In the United States the position is better than with us, for there the Council of Pharmacy and Chemistry of the American Medical Association provides an organization for the critical and impartial testing of the therapeutic claims made for new preparations. We have no organization of this kind; the only factor limiting such claims is the sense of responsibility of the firms concerned, and this varies much. Unfortunately a vicious circle has been established. The claims made for many of the new compounds represent the optimism of the vendor rather than a disinterested and balanced judgement based on controlled observations. The direct harm done is perhaps not very great, because most medical practitioners have learnt to allow a heavy discount off such claims. But the indirect damage is considerable, because the introduction of new compounds has come to be regarded as a field of medical research in which those careful of their reputation must step warily. Consequently it is difficult for firms to get disinterested opinions about the pharmacological and clinical value of new drugs. Dr. Leake suggests that in the United States there should be closer co-operation between commercial concerns and university laboratories of pharmacology. "Such an arrangement," he remarks, "might be profitable in many ways. The company would be assured of careful and unbiased judgement on the pharmacology, toxicology, and worthiness of clinical trial of their new preparations, while the pharmacological laboratory might secure much-needed help in the prosecution of more strictly scientific problems." There are, however, obvious dangers in such an arrangement, for a laboratory which becomes dependent on commercial firms for its support ceases to be an independent and impartial authority. It would be preferable to have some central authority to arrange for the necessary pharmacological and clinical investigations of substances which appear worthy of a careful trial.

WAYS THEY HAD IN THE ARMY.

"SOME aspects of administration"[1] was originally a lecture delivered at the Royal Army Medical College in September of last year. Lieut.-Colonel M. B. H. Ritchie is no worshipper of big words and obscure ideas. Couched in simple colloquial language and innocent of any flowers of speech, his contribution is a breezy discourse which will strike a chord of sympathy in many hearts. Colonel Ritchie remarks that war administration hinges on personality. His own personality is stamped across the pages of his lecture: obviously one who has the happy faculty of getting things done, who suffers fools sadly, and is somewhat impatient of delay. Among the many eccentric types that emerged from the stress of war was the gentleman, vested with a slight brief authority, who took a peculiar delight in obstructing matters. It was a strange aspect of human development, hard to understand, and the cause of much bitterness. How many medical officers, anxious to get on with the job, eager for the war to be done and won, suffered at seeing good recommendations and sensible suggestions condemned to the obscurity and oblivion of a pigeon-hole! Colonel Ritchie deals faithfully with such hinderers in the wheels of progress. "But Heaven preserve me from the professional obstructionist in war. The history of military disasters is a continuous record of obstructionism. Your obstructionist is able, capable, argumentative, full of plausible reasons. You can do nothing with him. If one is in the way, however far down the military scale, he will put a road-block across your route to success. He is incurable. There is only one thing to be done with him. Send him home." Again, the stout middle-aged gentlemen of senior rank, who spent their days in high places, devouring regulations, trying to do everything themselves, and writing precise and detailed memoranda, instead of going outside and seeing that the work was done, might have learnt a lesson from the following: "You will be led to delegate as much as you can, and it is sound. Do not get your mind filled up with details. There is no room for the big things if you do. You must trust your subordinates; give them as much autonomy as you can, but know what they are doing. You yourself must never get clogged up with correspondence, so that you have to stay in when you ought to be going around. There is no special advantage in having a meticulous mind in a high appointment." There is much else that is of interest in this attractive article. It is so good that we venture to commend it to the Medical Director-Generals of the three Services for circulation to all medical officers of the regular and auxiliary forces, in order that they may read, mark, learn, and inwardly digest.

MATERNAL AND CHILD WELFARE IN AUSTRALIA.

ON the invitation of the Prime Minister of the Commonwealth of Australia, Dame Janet M. Campbell, M.D., senior medical officer for maternal and child welfare to the Ministry of Health, recently paid a visit to each of the States of the Commonwealth for the purpose of studying the organizations for maternal and child welfare, and advising the Government on the development of these services. In her report, just issued by the Department of Health of the Commonwealth,[1] Dame Janet Campbell presents a statement of the present position in Australia in regard to maternal and infant mortality and morbidity, and of the existing facilities for maternal and child welfare, and indicates the directions in which she believes improvement could usefully be made. Expressed briefly, her proposals are that the Governments must be prepared to spend more money, though not more than would be enough to secure those essential facilities which the personal resources of the people themselves are unable to supply; that departments must assume more actively their responsibility for those important branches of public health administration that concern maternal and infant welfare; and that "voluntary agencies must prepare themselves to surrender for the greater good some portion of their, perhaps, over-cherished independence." We hope on a later occasion to consider this report in more detail.

GAS FIRES.

THE convenience of gas fires is beyond question. The readiness with which they can be brought into action makes them invaluable for rooms in occasional use, and the saving of domestic labour is a boon in the office and household. Until recent years, however, they have suffered from at least two serious disadvantages—their ugliness, and the constant hiss of their burners, so different from the comfortable sound of the coal fire. But the modern gas burner is almost silent, and well-known architects have now turned their attention to designing grates which are agreeable in form and setting and yet not mere copies or adaptations of the coal-burning fireplace. In *Gas Fires and Their Settings*[2] the late Sir Lawrence Weaver shows how successful are many of these designs, and how fitly they are planned in relation to the rooms where they are installed. The volume contains admirable illustrations of gas fires designed by Morley Horder, Walter Tapper, Guy Dawber, Giles Scott, Hubert Lidbetter, to name but a few of the famous architects whose work is represented in its pages. From a study of these pictures it may be gathered that the greatest measure of success is attained when the

[1] H. J. Green, Government Printer, Canberra, Australia.
[2] *Gas Fires and Their Settings*. By Sir Lawrence Weaver, K.B.E., F.S.A., Hon.A.R.I.B.A. London: The Fanfare Press. 1929. (7s. 6d.)

designer makes it clear that the fire is a gas fire with a character of its own, and that the result is least happy when he contrives an adaptation of some well-known type of fireplace. A combination of gas fittings with a pedestal basket grate of Queen Anne period seems ridiculous; the delightful openness of the dog-basket grate looks desolate when filled with hard immobile incandescent "fuel"; nor does a sprinkling of "artificial coal" help the eye—it seems rather to aggravate the offence. But there is ample evidence—as, for example, in the illustration showing a corner of a doctor's waiting-room—that the effort to secure appropriate designs for gas fires is meeting with success. Perhaps the complete breakaway from the hearth tradition shown in Morley Horder's design is an indication of the wisest line of advance. Here there is no hearth or curb; the wall skirting is carried round beneath the fire, and the fire itself is set within a metal frame, which has doors to be opened when the gas is alight and closed when it is turned off; the surround is slightly in advance of the wall level, and not recessed. However strong a preference anyone may feel for the coal fire, he has to acknowledge that with such a design the gas fire is not for ever proclaiming its inferiority complex, but asserting its own dignity as something useful and seemly.

THE MENTAL TREATMENT BILL.

THE second reading debate in the House of Commons on the Government's Mental Treatment Bill, of which our Parliamentary Correspondent gives a full account at page 365, was noteworthy for a clear and straightforward speech by the Minister of Health, and for the sympathy displayed towards the objects of the bill by members of all parties. As in the Lords, so in the Commons, a desire was expressed by several speakers that better protection should be given to the certifying medical practitioner than that provided in Clause 16. It is to be hoped that this point—of great immediate concern to the medical profession, and indirectly of no less importance to the public—will be kept in the forefront during the committee stage in the Commons. The reference to "non-volitional cases" by Sir Boyd Merriman (Solicitor-General in the late Government) contrasted agreeably with Lord Brentford's preoccupation in the House of Lords with "the liberty of the subject," and emphasized the Opposition's acceptance of this bill as non-contentious, or at least non-party.

SIR CHARLES HASTINGS LECTURE.

THE third of the series of Sir Charles Hastings Lectures, inaugurated by the British Medical Association for the purpose of offering to the public information by the highest authorities on matters of general public health interest, will be delivered in the Great Hall of the British Medical Association's House in London on Wednesday, March 12th, at 8 p.m. This year's lecturer is Sir Andrew Balfour, K.C.M.G., M.D., director of the London School of Hygiene and Tropical Medicine, and his subject will be "Health and Empire." The chair will be taken by Lord Riddell, president of the Royal Free Hospital, and after the lecture relevant questions in writing will be invited. Admission is free, by tickets obtainable on application to the Financial Secretary, B.M.A. House, Tavistock Square, W.C.1. Seats not occupied by ticket holders by 7.50 p.m. will be available for other members of the public.

THE Medical Research Council has appointed Air Vice-Marshal David Munro, C.B., C.I.E., M.B., on his retirement as Director of Medical Services, Royal Air Force, to be secretary of the Industrial Health Research Board, in succession to Mr. D. R. Wilson, C.B.E., lately appointed Deputy Chief Inspector of Factories at the Home Office. The appointment will take effect on March 1st, 1930.

THE eighth biennial Sydney Ringer Memorial Lecture will be delivered at University College Hospital Medical School on Monday, March 17th, at 5 p.m., by Professor E. B. Verney, M.B., F.R.C.P., whose subject is "The reserve forces of the kidney." Sir John Rose Bradford, President of the Royal College of Physicians, will take the chair. The lecture is open to all qualified practitioners and medical students.

DR. J. A. GLOVER'S three Milroy Lectures on the incidence of rheumatic diseases will be given before the Royal College of Physicians of London, Pall Mall East, S.W., on February 27th and March 4th and 6th at 5 p.m. Members of the medical profession will be admitted on presentation of visiting card.

MEDICAL CONGRESSES, 1930.

THE following congresses and conferences on medical and allied subjects have been announced for 1930. Particulars are given below in the following order: Date, name of organizing body, place of meeting, name of person to whom inquiries should be addressed. More detailed information as to these meetings is given from time to time, as it becomes available, in the news columns of the *British Medical Journal*.

April 7–10.—German Society for Internal Medicine. Wiesbaden. Professor Volhard, Süd 10, Medizinische Klinik, Frankfort.

April 9–13.—Berlin Balneological Society. Bad Elster. Dr. Max Hirsch, Steglitzstrasse 66, Berlin, W.35.

April 24–25.—German Society for Psychiatry. Stuttgart.

May 6–10.—International Congress for Mental Hygiene. Washington. Mr. Clifford Beers, 370, Seventh Avenue, New York City.

May 17.—International Exhibition of Hygiene. Dresden.

May 19–21.—International Congress on Malaria. Algiers. General Secretary, Institut Pasteur, Algiers.

May.—Italian Congress for Medical Radiology. Turin.

June 4–9.—Royal Institute of Public Health. Portsmouth. Secretary of Institute, 37, Russell Square, W.C.1.

June 5.—International Congress of Orthopaedics. Paris.

June 12–13.—German Society for Tuberculosis. Norderney.

June 21–28.—Royal Sanitary Institute. Margate. Secretary of Institute, 90, Buckingham Palace Road, S.W.1.

June 25.—International Society of Microbiology. Paris.

June 28 to July 2.—Journées Médicales de Bruxelles. Brussels.

July 10–12.—Oxford Ophthalmological Congress. Oxford. Mr. C. G. Russ Wood, 12, St. John's Hill, Shrewsbury.

July 26–27.—Belgian Congress of Neurology and Psychiatry. Liège. Dr. Leroy, 30, Rue Hemricourt, Liège.

August 3–10.—International Society of Sexology. London. Professor F. A. E. Crew, The University, Edinburgh.

August 4–9.—International Veterinary Congress. London. Dr. F. Bullock, 10, Red Lion Square, W.C.1.

August 5–9.—International Congress of Dermatology and Syphilology. Copenhagen. Dr. S. Lumholt, 45, Raadhusplads, Copenhagen.

August 12–15.—International Union against Tuberculosis. Oslo. Secretary of Union, 2, Avenue Velasquez, Paris, VIII.

August 17–20.—International Congress of Paediatrics. Stockholm.

August 26–29.—British Medical Association Annual Meeting. Winnipeg. Financial Secretary of British Medical Association, Tavistock Square, London, W.C.1.

August to September.—International Congress of Neurologists. Bern.

August.—International Congress on Miners' Phthisis. Johannesburg. International Labour Office, Geneva.

August.—Congress of Northern Neurologists. Stockholm.

September 4–8.—International Congress of Physiotherapy. Liège. Dr. Dubois-Trépagne, 25, Rue Louvreux, Liège.

September 22–27.—International Congress of the History of Medicine. Rome.

October 9.—Association Professionnelle Internationale des Médecins. Geneva. Dr. F. Decourt, Mitry-Mory (Seine-et-Marne), France.

1930.—International Cancer Conference. Madrid.

1930.—German Congress of Natural Science and Medicine. Königsberg.

1930.—Congress of Equatorial Medicine. Guayaquil, Ecuador.

Collective Investigation

INTO

THE AFTER-HISTORY OF GASTRO-ENTEROSTOMY.

Report by

ARTHUR P. LUFF, C.B.E., M.D., B.Sc., F.R.C.P.,
CONSULTING PHYSICIAN TO ST. MARY'S HOSPITAL; HONORARY DIRECTOR OF THE RESEARCH.

THE results of the operation for duodenal ulcers have been published in Part I (*British Medical Journal*, December 7th, 1929); the results for pyloric ulcers have been published in Part II, and for perforated duodenal and pyloric ulcers in Part III (*British Medical Journal*, December 14th, 1929). The present report deals similarly with the gastric ulcers. There were 645 reports of the results of operations for gastric ulcer. They consisted of 538 cases of ordinary gastric ulceration, 65 cases of hour-glass constriction, and 42 cases of perforated gastric ulcers. As it is somewhat unusual to have the records of 65 cases of hour-glass constriction it was considered advisable to prepare a separate report on those cases, and also on the cases of perforation.

PART IV.—GASTRIC ULCERS.

The answers to the various questions in connexion with the 538 cases of ordinary gastric ulceration have been carefully collated, and the results are embodied in the following tables.

TABLE I.—*Sex Incidence.*

Number of cases	538
Males (percentage)	66.2
Females (percentage)	33.8

This table shows that twice as many cases occur among males as among females.

TABLE II.—*Age Incidence (at Time of Operation).*

Age.	Percentage.
19-30 years	9.0
30-40 ,,	27.3
40-50 ,,	38.0
50-60 ,,	20.3
60-70 ,,	5.4

This table shows that the majority of patients with gastric ulceration were operated on between 30 and 50 years of age. Of the patients operated on between 19 and 30 years, two only were 19 years of age.

TABLE III.—*Position or Site of Ulcer.*
(Information on this point was given in 523 cases, including the hour-glass cases.)

Position or Site.	No. of Cases.	Percentage.
Lesser curvature	377	72.2
Near pylorus	56	10.7
Posterior wall	55	10.5
Anterior wall	16	3.0
Cardiac end	14	2.6
Greater curvature	5	1.0

TABLE IV.—*Ulcer Adherent or Non-adherent.*
(Information on these points was given in 167 cases, including the hour-glass cases.)

	No. of Cases.	Percentage.
Adherent	159	95.2
Non-adherent	8	4.8

TABLE V.—*Type of Operation.*

Type of Operation.	No. of Cases.	Percentage.
Posterior gastro-enterostomy	263	48.9
Posterior gastro-enterostomy and excision of ulcer	111	20.6
Partial gastrectomy with anastomosis to jejunum	101	18.8
Anterior gastro-enterostomy	23	4.1
Posterior gastro-enterostomy and cauterization of ulcer	13	2.4
Anterior gastro-enterostomy and jejunojejunostomy	11	2.0
Anterior gastro-enterostomy and excision of ulcer	5	
Posterior gastro-enterostomy and embedding of ulcer	5	
Sleeve resection and posterior gastro-enterostomy	4	17 — 3.2
Sleeve resection	2	
Anterior gastro-enterostomy and cauterization of ulcer	1	

In addition, appendicectomy was performed in 9.8 per cent., and cholecystotomy in 0.7 per cent. of the cases. In some of the cases the reasons given for performing anterior gastro-enterostomy were that the stomach was either too fixed or that there was insufficient room for performing the posterior operation.

The reasons for operating were given in 417 cases. They are recorded in the following table.

TABLE VI.—*Reasons for Operating.*

Symptoms.	No. of Cases.	Percentage.
Pain	411	98.6
Vomiting	285	68.3
Haematemesis	94	22.5
Haematemesis and melaena	9	2.0
Melaena	7	1.7
Loss of weight	35	8.4

Vomiting and haematemesis were both much more frequent in the gastric ulcer cases than in the duodenal and pyloric, but melaena was much more frequent in the duodenal cases than in the gastric and pyloric.

The direct results of operation in the 538 cases were as follows.

TABLE VII.—*Results of Operation.*

Result.	No. of Cases.	Percentage.
Good recovery	487	90.5
Delayed recovery	3	0.6
Death	48	8.9

The post-operative mortality is considerably higher than the 5.0 per cent. mortality among duodenal ulcers and the 2.6 per cent. mortality among pyloric ulcers.

The results in 299 cases submitted to *x*-ray examination prior to operation are shown in the following table.

TABLE VIII.—*Results of X-Ray Examination.*

Result.	Percentage.
Positive	54.9
Negative	18.0
Delay in emptying	27.1

In 105 cases test meals were employed prior to operation. The results are shown in the following table.

TABLE IX.—*Results of Test Meals.*

Result.	Percentage.
Hyperchlorhydria	40.0
Low acidity	52.4
No free hydrochloric acid	7.6

AFTER-HISTORIES OF THE OPERATION CASES.

The 538 cases dealt with in Tables I, II, V, and VII include 392 cases in which the after-histories were given, 26 cases in which the after-histories consisted only of statements that the patients were in good health at some specified time after operation, and 120 cases in which no after-history was given. For the preparation of the after-history statistics the 392 cases only are employed. In the majority of these cases the questions relating to the after-history were all answered, but as in a certain number of cases some of the questions were left unanswered, the statistics in the following tables have been worked out as percentages of the numbers of the answers to the respective questions.

The after-history inquiries were directed to the elucidation of the same points as in connexion with the duodenal ulcers (see Part I, *British Medical Journal*, December 7th, 1929, p. 1075).

TABLE X.—*Pain or Other Discomfort After Food.*
(Information on these points was given in 325 cases.)

	No. of Cases.	Percentage.
No pain or discomfort	250	74.5
Occasional slight pain or discomfort	50	15.0
Temporary pain or discomfort (in most cases soon after operation)	23	7.0
Severe pain or discomfort	12	3.5

TABLE XI.—*Diarrhœa.*
(Diarrhœa occurred in 18 cases out of the 392.)

Diarrhœa.	No. of Cases.	Percentage.
Slight	16	4.1
Severe	2	0.5

TABLE XII.—*Constipation.*
(Constipation occurred in 54 cases out of the 392.)

Constipation.	No. of Cases.	Percentage.
Slight	46	11.7
Severe	8	2.0

TABLE XIII.—*Food Able to be Taken.*
(Information as to diet was given in 320 cases.)

	No. of Cases.	Percentage.
Full diet	242	73.3
Certain articles of diet avoided	88	26.7

Among the 88 cases in which some modification of the diet was necessary, 45 avoided some form or forms of protein food (beef, mutton, veal, pork, bacon, cheese, eggs), 31 avoided some form or forms of carbohydrate food (vegetables, pastry, fats, fruits), and 12 avoided some form or forms of both protein and carbohydrate foods. Therefore, of those on a modified diet, 51 per cent. were obliged to avoid some form of protein, 35 per cent. some form of carbohydrate, and 14 per cent. some form of both protein and carbohydrate.

Information as to the time of return to work after operation was given in 280 cases. In a certain number of other cases it was stated that the individuals were either of the leisured classes doing no work, or were past the age for work. The particulars are given in the following table.

TABLE XIV.—*Time of Return to Work After Operation.*

Time of Return to Work.	No. of Cases.	Percentage.
1 to 2 months	59	21.1
2 to 3 „	152	54.3
3 to 4 „	34	12.1
4 to 6 „	23	8.2
Over 6 „	12	4.3

This table shows that 75.4 per cent. returned to work within three months from the date of the operation. With regard to those that did not return to work till after three months, the reasons given in many of the cases were that there was no immediate necessity for return, or that work was not available at the time.

TABLE XV.—*Work Capacity.*
(Information on this point was given in 316 cases.)

Work Capacity.	No. of Cases.	Percentage.
Full work	285	92.0
Light work	21	6.7
Unable to work	4	1.3

TABLE XVI.—*Weight After Operation.*
(Information on this point was given in 327 cases.)

Weight.	No. of Cases.	Percentage.
Gained	245	74.9
Constant	61	18.7
Lost	21	6.4

TABLE XVII.—*Condition of Health and Well-being After Operation.*
(Information on this point was given in 332 cases.)

Health.	No. of Cases.	Percentage.
General improvement of health	293	89.8
Fair improvement of health	11	3.3
Slight improvement of health	13	3.9
No improvement of health	10	3.0

Subsequent Medical Treatment Required.

A few cases required laxatives, astringents, and occasional bismuth and sodium bicarbonate. Several cases had subsequent medical treatment, but the nature of it was not specified.

TABLE XVIII.—*Number of Years After Operation during which Patients were under Observation, or during which Reliable Information was Obtained.*
(Definite information on this point was given in 331 cases.)

Years under Observation.	No. of Cases.	Percentage.
2-3 years	9	2.7
3-4 „	41	12.4
4-5 „	87	26.2
5-6 „	76	23.0
6-7 „	56	16.9
7-8 „	41	12.4
8-9 „	21	6.4

This table shows that 85 per cent. of the patients were under reliable observation for periods ranging from four to nine years.

Classification of Results.

The classification adopted is the same as that used in connexion with duodenal ulcers (see Part I, *British Medical Journal*, December 7th, 1929, p. 1076).

TABLE XIX.—*Classification of Results.*
(The results returned enabled this classification to be made in 334 cases.)

Classification.	No. of Cases.	Percentage.
Very good	243	73.3
Good	54	16.1
Fair	18	5.4
Poor	14	4.2

These are the late results of the various operations enumerated in Table V, and were obtained from the cases in which after-histories were given. As the main merits

of the various operations are represented by the percentage of "very good" results, in that they show the number of patients restored to full health, able to eat anything over periods of some years, and able to resume full work, it was considered advisable to compare the "very good" results in the three principal operations performed, together with the respective post-operative mortality. The three operations which constitute 92 per cent. of all the operations that were performed are: (1) posterior gastro-enterostomy combined with excision, cauterization, or infolding of the ulcer; (2) partial gastrectomy with anastomosis to jejunum; and (3) posterior gastro-enterostomy without interference with the ulcer. These statistics have been worked out, and are embodied in the following table.

TABLE XX.

Operation.	Very good results (percentage of the cases, with after-histories).	Post-operative Mortality (percentage of all cases).
Posterior gastro-enterostomy combined with excision, cauterization or infolding of ulcer	91.7	4.6
Partial gastrectomy with anastomosis to jejunum	63.6	6.0
Posterior gastro-enterostomy without interference with the ulcer	50.9	11.4

This table shows that the operation of posterior gastro-enterostomy, combined with removal or infolding of the ulcer, gives the best results and the lowest mortality in the operative treatment of gastric ulceration, whereas the operation of posterior gastro-enterostomy without interference with the ulcer gives poor results and a very high mortality. As to the position of the operation of partial gastrectomy in this table it is only right to mention that the results in connexion with that operation are based on 101 cases only. For explanation of the post-operative mortality column in this table reference should be made to Table XXVI in this report.

Occupation.

The occupations were given in 525 cases of gastric ulceration, including the cases of hour-glass constriction and perforation, and have been classified as follows.

TABLE XXI.—*Occupational Incidence.*

Occupation.	No. of Cases.	Percentage.
Domestic workers	163	31.0
Mechanics and skilled artisans	81	15.4
Labourers	80	15.3
Shop workers	42	8.0
Factory workers	40	7.6
Clerks	21	4.0
Farmers and land workers	20	3.8
Professional and leisured classes	9	1.7
Miners	3	0.6
Various occupations	66	12.6

Domestic workers (female) were responsible for 15 per cent. of the duodenal and pyloric ulcers, whereas it will be seen from the above table that the same class is responsible for 31 per cent. of the gastric ulcers. The total number of females in the gastric ulcer group is 192, of which 163—that is, 85 per cent.—were domestic workers. The great majority of the returns received in this investigation are of hospital patients, so that the above figures give no indication as to the occurrence of the disease among the bulk of the middle and upper classes.

Secondary Gastro-jejunal Ulcers.

Number.—Three ulcers of this type—that is, 0.8 per cent.—occurred among the 392 cases in which after-histories were given.

Sex.—Two males and one female.

Age.—Two between 40 and 50 years of age, and one between 50 and 60.

Symptoms.—Pain in all three cases, vomiting in one case, and haematemesis in one case.

Periods after Original Operation at which Symptoms occurred necessitating Operation for Gastro-jejunal Ulceration.—The periods in the three cases were respectively one year, one year and nine months, and one year and ten months.

Operation.—Partial gastrectomy with good recovery in the three cases.

Second Operations required for Intercurrent Lesions after the Original Operation for Gastric Ulceration.

Seven of these operations—that is, 1.8 per cent.—were required among the 392 cases in which after-histories were given. One was between 20 and 30 years of age, one between 30 and 40, four between 40 and 50, and one between 50 and 60. Particulars of the individual cases are given.

1. Persistent vomiting for eight weeks after first operation. Stoma resected; death five days later from peritonitis due to a leak.

2. Pain, vomiting, and haematemesis three months after first operation from formation of a second gastric ulcer. Partial gastrectomy done; fair recovery.

3. Pain and vomiting one year after first operation from persistent lesser curve ulcer. Partial gastrectomy done; good recovery.

4. Pain and vomiting two years after first operation from persistent lesser curve ulcer. Partial gastrectomy done; good recovery.

5. Pain two and a half years after first operation from duodenal dilatation. Duodeno-jejunostomy done; good recovery.

6. Recurrence of symptoms four and a half years after first operation from a fresh ulcer. Excision done; good recovery.

7. Pain five years after first operation from adhesions involving transverse colon. Adhesions divided; good recovery.

Secondary Haemorrhage.

Number.—Four cases of secondary haemorrhage—that is, 1.0 per cent.—occurred among the 392 cases in which after-histories were given.

Sex.—Three males and one female.

Age.—One between 20 and 30 years of age, and three between 30 and 40.

Nature of Haemorrhage.—Haematemesis in three cases, and melaena in one.

Periods at which Haemorrhage started after Operation.—One at ten days; one at nine months; one at four years; one had three attacks at one and a half years, five years, and six years.

Treatment.—Three had medical treatment, and one had rest only; good recovery in all cases.

Analysis of the Post-operative Mortality.

Among the 538 cases of gastric ulceration 7 deaths occurred from another lesion some years after the operation and quite unconnected with it. As these 7 cases up to the time of death were free from all symptoms connected with the ulceration, these deaths are not included among the post-operative deaths.

The number of post-operative deaths out of the 538 cases was 48—that is, 8.9 per cent. These are the deaths that occurred as a direct result of the operations for gastric ulcers, and do not include the one death from an intercurrent lesion previously referred to.

Sex.—Of the 48 deaths, 66.7 per cent. occurred amongst males, and 33.3 per cent. amongst females—a ratio which is the same as that of the sex incidence of the disease.

TABLE XXII.—*Age Incidence of Deaths.*

Age.	Percentage of Deaths.
30-40 years	16.7
40-50 ,,	37.5
50-60 ,,	37.5
60-70 ,,	8.3

TABLE XXIII.—*Time of Occurrence of Death After Operation.*

Time.	Percentage of Deaths.
1-6 days	57
7-14 ,,	21
2-3 weeks	10
3-4 ,,	10
4-5 ,,	2

Among the 48 cases haemorrhage occurred as a symptom prior to operation in 23 per cent. of the cases. It therefore appears, as in the cases of the duodenal and pyloric ulcers, that the risk of a fatal post-operative result is not increased by the occurrence of haemorrhage prior to the operation.

TABLE XXIV.—*Cause of Death.*

Cause of Death.	No. of Cases.
Shock	19
Pneumonia	6
Haematemesis	5
Cardiac failure (fatty heart)	3
Bronchitis	1
Empyema	1
Tetany	1
Septic infection	1
Embolism of pulmonary artery	1
Hemiplegia	1
Cause not stated	9

Comparison of the Post-operative Mortality in Relation to the Site of the Gastric Ulcer.

If a comparison is made of the post-operative mortality occurring amongst ulcers according to their special positions or sites in the stomach, it appears that the mortality is much lower for lesser curvature ulcers and is much higher for ulcers on the posterior wall than the average post-operative mortality. This is shown in the following table.

TABLE XXV.

Position or Site of Ulcer.	No. of Cases.	No. of Deaths.	Percentage of Deaths.
Lesser curvature	377	19	5.0
Anterior wall	16	1	6.2
Near pylorus	56	6	10.7
Cardiac end	14	2	14.3
Posterior wall	55	13	23.6

Comparison of the Post-operative Mortality of the Three Principal Operations.

The 8.9 per cent. mortality represents the death rate after the performance of the 538 operations detailed in Table V. Of these operations, 129 were posterior gastro-enterostomy, combined with excision, cauterization, or infolding of the ulcer; 101 were partial gastrectomy with anastomosis to jejunum; 263 were posterior gastro-enterostomy without any interference with the ulcer; and 45 were other operations (mainly anterior gastro-enterostomy). The comparison of the post-operative mortality of the three principal operations, as shown in the following table, has already been referred to in Table XX.

TABLE XXVI.

Type of Operation.	No. of Cases.	No. of Deaths.	Percentage of Deaths.
Posterior gastro-enterostomy combined with excision, cauterization, or infolding of ulcer	129	6	4.6
Partial gastrectomy with anastomosis to jejunum	101	6	6.0
Posterior gastro-enterostomy without interference with the ulcer	263	30	11.4
Other operations (mainly anterior gastro-enterostomy)	45	6	13.3

If these death percentages are proportionately averaged the 8.9 per cent. post-operative mortality for the whole of the cases is obtained. These figures show, so far as any useful deductions can be drawn from groups of 129 and 101 cases, that the operation of posterior gastro-enterostomy, combined with removal or infolding of the ulcer, has the lowest mortality, while that of posterior gastro-enterostomy alone has a very high mortality.

Carcinoma Developing at the Site of Ulcers.

No authenticated case was reported in the whole series. In one case the patient, aged 69 at the time of death, developed gastric pain nearly four years after the operation for gastric ulcer. A laparotomy was done and a hard non-removable mass was felt at the site of the old ulcer. Death occurred on the following day from shock. In answer to a special letter sent to the surgeon who had charge of the case, he replied that he could give no opinion as to the nature of the mass.

In a second case the patient, aged 36 years at the time of operation, developed symptoms five years after operation, and a *diagnosis was made by x-ray examination* of inoperable carcinoma of the stomach. The patient continued to lose weight, and the mass was easily palpable. Death occurred one year after the commencement of the fresh symptoms, but no post-mortem examination was held.

BRIEF SUMMARY OF RESULTS.

Gastric ulceration is twice as common in males as in females.

The liability to gastric ulceration rapidly diminishes after 50 years of age, as is also the case with both duodenal and pyloric ulceration.

Posterior gastro-enterostomy, with or without removal or infolding of the ulcer, was performed in 73 per cent. of the cases, and partial gastrectomy with anastomosis to jejunum in 19 per cent.

Vomiting (with or without haemorrhage) was a symptom in 93 per cent. of the cases, as compared with 53 per cent. amongst the duodenal ulcers, and 64 per cent. amongst the pyloric ulcers.

A low acidity of the gastric juice was present in 60 per cent. of the cases submitted to test meals.

Neither diarrhoea nor constipation is a marked result of operation, but, as in the cases of duodenal and pyloric ulcers, constipation of a mild character is more frequent than diarrhoea.

About one-quarter of the patients operated on made some modification in diet. Of these, 51 per cent. avoided some form of protein, 35 per cent. some form of carbohydrate, and 14 per cent. some form of both protein and carbohydrate.

Three-fourths of the patients returned to full work within three months of the date of the operation.

General improvement of health and well-being occurred in 90 per cent. of the cases with after-histories.

The operation of posterior gastro-enterostomy, combined with removal or infolding of the ulcer, gives the best results and the lowest mortality.

Secondary gastro-jejunal ulcers occurred in 0.8 per cent. of the cases, as compared with 2.8 per cent. for duodenal ulcers and 0.9 per cent. for pyloric ulcers.

Secondary haemorrhage occurred in 1.0 per cent. of the cases, as compared with 2.4 per cent. for duodenal ulcers and 1.2 per cent. for pyloric ulcers.

The post-operative mortality for all operations was 8.9 per cent., the mortality being highest in patients from 40 to 60 years of age. The operation of posterior gastro-enterostomy, combined with removal or infolding of the ulcer, had a post-operative mortality of 4.6 per cent.; partial gastrectomy with anastomosis to jejunum had a post-operative mortality of 6.0 per cent.; posterior gastro-enterostomy alone had a post-operative mortality of 11.4 per cent.

No authenticated case of carcinoma developing at the site of an ulcer was reported in the whole series.

PART V.—HOUR-GLASS CONSTRICTION.

As previously mentioned, it was considered advisable to prepare a separate report on these cases. The results may be of use for future reference, but as the number of the cases is comparatively small very few comments on the results are made.

TABLE I.—*Sex Incidence.*

Number of cases	65
Males (percentage)	15.4
Females (percentage)	84.6

TABLE II.—*Age Incidence (at Time of Operation).*

Age.	Percentage.
20-30 years	4.8
30-40 ,,	28.6
40-50 ,,	25.4
50-60 ,,	33.3
60-70 ,,	7.9

TABLE III.—*Type of Operation.*

Type of Operation.	No. of Cases.	Percentage.
Partial gastrectomy with anastomosis to jejunum	33	50.7
Posterior gastro-enterostomy	13	20.0
Anterior gastro-enterostomy	9	13.8
Posterior gastro-enterostomy and excision of ulcer	8	12.3
Hour-glass incised longitudinally and sewn transversely	1	1.6
Double gastro-jejunostomy	1	1.6

In addition, appendicectomy was performed in 3.1 per cent. of the cases, and cholecystotomy in 3.1 per cent.

The reasons for operating were given in 55 cases. They are recorded in the following table.

TABLE IV.—*Reasons for Operating.*

Symptoms.	No. of Cases.	Percentage.
Pain	53	96.3
Vomiting	46	83.6
Haematemesis	13	23.6
Haematemesis and melaena	2	3.6
Loss of weight	5	9.1

The direct results of operation in the 65 cases were as follows.

TABLE V.—*Results of Operation.*

Results.	No. of Cases.	Percentage.
Good recovery	55	84.6
Delayed recovery	2	3.1
Death	8	12.3

The results in 43 cases submitted to *x*-ray examination prior to operation are shown in the following table.

TABLE VI.—*Results of X-Ray Examinations.*

Result.	Percentage.
Positive	93.0
Negative	2.3
Delay in emptying	4.7

In 18 cases test meals were employed prior to operation. The results are shown in the following table.

TABLE VII.—*Results of Test Meals.*

Result.	Percentage.
Hyperchlorhydria	16.7
Low acidity	77.8
No free hydrochloric acid	5.5

AFTER-HISTORIES OF THE OPERATION CASES.

The 65 cases include 52 cases in which the after-histories were given, 4 cases in which the after-histories consisted only of statements that the patients were in good health at some specified times after operation, and 9 cases in which no after-history was given. For the preparation of the after-history statistics the 52 cases only are employed, and, as in the previous reports, the statistics have been worked out as percentages of the numbers of the answers to the respective questions.

TABLE VIII.—*Pain or Other Discomfort After Food.*
(Information on these points was given in 44 cases.)

	No. of Cases.	Percentage.
No pain or discomfort	38	86.3
Occasional slight pain or discomfort	4	9.1
Temporary pain or discomfort	1	2.3
Severe pain or discomfort	1	2.3

Diarrhoea.—Slight diarrhoea occurred in 2 cases out of the 52.

Constipation.—Slight constipation occurred in 7 cases out of the 52.

TABLE IX.—*Food Able to be Taken.*
(Information as to diet was given in 44 cases.)

	No. of Cases.	Percentage.
Full diet	37	84.1
Certain articles of diet avoided	7	15.9

TABLE X.—*Time of Return to Work After Operation.*
(Information was given in 42 cases.)

Time of Return to Work.	No. of Cases.	Percentage.
1 to 2 months	5	11.9
2 to 3 ,,	27	64.3
3 to 4 ,,	4	9.5
4 to 6 ,,	4	9.5
Over 6 ,,	2	4.8

This table shows that 76.2 per cent. returned to work within three months from the date of the operation.

TABLE XI.—*Work Capacity.*
(Information on this point was given in 43 cases.)

Work Capacity.	No. of Cases.	Percentage.
Full work	40	93.0
Light work	3	7.0

TABLE XII.—*Weight After Operation.*
(Information on this point was given in 43 cases.)

Weight.	No. of Cases.	Percentage.
Gained	37	86.0
Constant	4	9.3
Lost	2	4.7

TABLE XIII.—*Condition of Health and Well-being After Operation.*
(Information on this point was given in 43 cases.)

Health.	No. of Cases.	Percentage.
General improvement of health	39	90.7
Fair improvement of health	2	4.7
Slight improvement of health	1	2.3
No improvement of health	1	2.3

TABLE XIV.—*Number of Years After Operation during which Patients were under Observation, or during which Reliable Information was Obtained.*
(Definite information was given in 41 cases.)

Years under Observation.	No. of Cases.	Percentage.
1-2 years	1	2.4
2-3 ,, ...	1	2.4
3-4 ,, ...	2	4.9
4-5 ,, ...	14	34.1
5-6 ,, ...	9	22.0
6-7 ,, ...	5	12.2
7-8 ,, ...	3	7.3
8-9 ,, ...	6	14.7

TABLE XV.—*Classification of Results.*
(The results returned enabled this classification to be made in 43 cases.)

Classification.	No. of Cases.	Percentage
Very good	36	83.7
Good	3	7.0
Fair	3	7.0
Poor	1	2.3

The same comparison follows as was made in Part IV of the "very good" results and the respective post-operative mortality of the various operations performed.

TABLE XVI.

Operation.	Very good results (percentage of the cases with after-histories).	Post-operative mortality (percentage of all cases).
Posterior gastro enterostomy combined with excision of ulcer	87.5	12.5
Partial gastrectomy with anastomosis to jejunum	57.6	15.1
Posterior gastro-enterostomy ...	46.1	7.7
Anterior gastro-enterostomy ...	44.4	11.1

Analysis of the Post-operative Mortality.

The number of post-operative deaths out of the 65 cases was 8—that is, 12.3 per cent.

Sex.—Of the 8 deaths, 3 occurred amongst males and 5 amongst females.

Age Incidence of Deaths.—Half occurred between 40 and 50 years of age, and half between 50 and 61 years of age.

Time of Occurrence of Death after Operation.—Seven deaths occurred between one and seven days, and one death occurred from broncho-pneumonia twenty-five days after operation.

Comparison of the Post-operative Mortality of the Various Operations Performed.

Type of Operation.	No. of Cases.	No. of Deaths.	Percentage of Deaths.
Posterior gastro-enterostomy	13	1	7.7
Anterior gastro-enterostomy	9	1	11.1
Posterior gastro-enterostomy combined with excision of ulcer	8	1	12.5
Partial gastrectomy with anastomosis to jejunum	33	5	15.1
Other operations	2	Nil	—

If these death percentages are proportionately averaged the 12.3 per cent. post-operative mortality for the whole of the cases is obtained.

Carcinoma Developing at the Site of Ulcer.—No case was reported in the whole series.

Brief Summary of Results.

Hour-glass constriction is much more common in females.

The liability to hour-glass constriction is fairly constant from 30 to 60 years of age.

A low acidity of the gastric juice was present in a large majority of the cases tested.

76.2 per cent. of the cases returned to full work within three months of the date of the operation.

General improvement of health and well-being occurred in 90 per cent. of the cases with after-histories.

The post-operative mortality was 12.3 per cent.

No case of carcinoma developing at the site of an ulcer was reported in the whole series.

PART VI.—PERFORATED GASTRIC ULCERS.

There were 42 reports of the results of operations for perforated gastric ulcers. These results may be of use for future reference, but as the number of the cases is small the only comments on the results are given in the summary at the end.

TABLE I.—*Sex Incidence.*

Number of cases	42
Males (percentage)	73.8
Females (percentage)	26.2

TABLE II.—*Age Incidence (at Time of Operation).*

Age.	Percentage
20-30 years	10.0
30-40 ,, ...	35.0
40-50 ,, ...	32.5
50-60 ,, ...	20.0
60-70 ,, ...	2.5

TABLE III.—*Position on Site of Ulcer.*
(Information on this point was given in 26 cases.)

Position on Site.	Percentage
Lesser curvature	46.2
Anterior wall	34.6
Near pylorus	15.4
Posterior wall	3.8

TABLE IV.—*Type of Operation.*

Type of Operation	Percentage
Closure of perforation and posterior gastro-enterostomy	90.5
Closure of perforation and anterior gastro-enterostomy	7.1
Partial gastrectomy and posterior gastro-enterostomy	2.4

TABLE V.—*Reasons for Operation.*

Symptoms.	Percentage
Pain	100.0
Vomiting	45.2
Haematemesis	4.7
Melaena	2.4

TABLE VI.—*Results of Operation.*

Result.	Percentage
Good recovery	71.4
Death	28.6

AFTER-HISTORIES OF THE OPERATION CASES.

The 42 cases dealt with in the above tables include 34 cases in which the after-histories were given, and 8 cases in which no after-history was given. For the preparation of the after-history statistics the 34 cases only are employed.

TABLE VII.—*Pain or Other Discomfort After Food.*
(Information on these points was given in 22 cases.)

	Percentage.
No pain or discomfort	54 6
Occasional or slight pain or discomfort	31.8
Temporary pain or discomfort (in most cases soon after operation)	13.6

Diarrhoea.—Slight diarrhoea occurred in 3.0 per cent. of the cases.

Constipation.—Slight constipation occurred in 11.8 per cent. of the cases.

TABLE VIII.—*Food Able to be Taken.*
(Information as to diet was given in 21 cases.)

	Percentage.
Full diet	71.4
Certain articles of diet avoided	28.6

TABLE IX.—*Time of Return to Work After Operation.*
(Information on this point was given in 21 cases.)

Time of Return to Work.	Percentage.
1-2 months	4.7
2-3 ,,	19.1
3-4 ,,	33.3
4-6 ,,	19 1
Over 6 ,,	23.8

TABLE X.—*Work Capacity.*
(Information on this point was given in 22 cases.)

Work Capacity.	Percentage.
Full work	86.4
Light work	13.6

TABLE XI.—*Weight After Operation.*
(Information on this point was given in 20 cases.)

Weight.	Percentage.
Gained	55 0
Constant	40.0
Lost	5.0

TABLE XII.—*Condition of Health and Well-being After Operation.*
(Information on this point was given in 22 cases.)

Health.	Percentage.
General improvement of health	77 3
Fair improvement of health	18.2
Slight improvement of health	4.5

TABLE XIII.—*Number of Years After Operation during which Patients were under Observation, or during which Reliable Information was Obtained.*
(Definite information on this point was given in 22 cases.)

Years under Observation.	Percentage.
3-4 years	31.8
4-5 ,,	18.2
5-6 ,,	13.6
6-7 ,,	18.2
7-8 ,,	13.6

TABLE XIV.—*Classification of Results.*
(The results returned enabled this classification to be made in 22 cases.)

Classification.	Percentage.
Very good	63 7
Good	13.6
Fair	18.2
Poor	4.5

No secondary gastro-jejunal ulcer occurred in the whole series.

No secondary haemorrhage occurred in the whole series.

Analysis of the Post-operative Mortality.

The number of post-operative deaths out of the 42 cases was 12—that is, 28.6 per cent.

Sex.—Nine of the deaths occurred among males, and 3 among females.

TABLE XV.—*Age Incidence of Deaths.*

Age.	Percentage of Deaths.
20-30 years	18.2
30-40 ,,	27.3
40-50 ,,	27.3
50-60 ,,	18.2
60-70 ,,	9.0

TABLE XVI.—*Time of Occurrence of Death After Operation.*

Time.	No. of Cases
1-6 days	5
7-14 ,,	4
6-7 weeks	1
Not stated	2

TABLE XVII.—*Cause of Death.*

Cause of Death.	No. of Cases.
Shock	2
Pneumonia	1
Subphrenic abscess	1
Erosion into transverse meso-colon	1
Cause not stated	7

Carcinoma developing at the Site of Ulcer.—No case was reported in the whole series.

Brief Summary of Results.

Perforated gastric ulcer was three times as common in males as in females.

Rather more than two-thirds of the perforations occurred between 30 and 50 years of age.

About 24 per cent. of the cases returned to full work within three months of the date of the operation. About 65 per cent. of the cases of perforated duodenal and pyloric ulcers returned to full work in the same period of time.

The results of the operations were satisfactory in about 77 per cent. of the cases that survived, as compared with the corresponding figure of about 89 per cent. for the perforated duodenal and pyloric ulcers.

The post-operative mortality was 28.6 per cent., as compared with the post-operative mortality of 13.6 per cent. among the perforated duodenal and pyloric ulcers.

No case of carcinoma developing at the site of an ulcer was reported in the whole series.

DEATHS FROM COAL GAS POISONING.

DEPARTMENTAL COMMITTEE'S REPORT.

THE report of the Departmental Committee appointed by the President of the Board of Trade "to consider the increase during recent years in the number of deaths ascribed to poisoning by coal gas supplied for domestic purposes, and to make recommendations as to any measures relating to the production and use of gas for domestic purposes which might be taken with a view to diminishing the number of such deaths," has now been issued.[1] This is the third Departmental Committee to inquire into gas poisoning, the first having sat in 1898, Lord Belper presiding, the second in 1921, with Sir William Pearce as chairman. The Rt. Hon. Sir Evelyn Cecil has been chairman of this last committee.

Deaths Ascribed to Coal Gas Poisoning.

Statistics revealing an increase in the number of gas suicides from 193 in 1918 to 1,191 in 1928, while accidental deaths merely rose from 102 to 163, have at first sight a sensational effect. The comments of the report, however, are reflective, non-alarmist, and intelligently aware that any statement concerning suicidal gas poisoning can be but a contribution towards some larger inquiry concerning the general problem of the growing tendency towards self-destruction, and its relations, not to coal gas in particular, but to the peculiar psychological and social conditions of the transitional post-war era. The great war, we are told incidentally, checked all forms of suicide, a fact that opens up an interesting field of psychiatric study. But during the post-war years of disillusionment and economic distress the rate of self-inflicted death has returned to its pre-war level, and that chiefly by way of coal gas poisoning. The slight increase in deaths by accident is easily accounted for by the growing numbers of gas consumers. The deaths by gas suicide, however, are probably underestimated, verdicts of "accident" in many cases masking suicide, because of the dubiety or sympathy of juries. We are warned that the statistics for 1929 will probably show an increase in accidental deaths from gas because of the excessively cold weather in the beginning of the year. One would naturally expect a similar increase in suicides, for the continuously bitter cold must have lowered the last vitality of many persons suffering from acute depression or financial distress.

The fact that gas poisoning has superseded drowning as the prevailing fashion in suicide has caused the committee to observe that many of its witnesses believe that the publicity given to accounts of gas suicides has an imitative or suggestive effect on people already disposed to self-destruction. Probably certain victims of a merely passive kind of depression might accept some such slight push over the verge when they might otherwise stay alive from sheer inactivity. And such, it had been supposed, might also yield to the accessibility of coal gas when they would hardly seek a more difficult death. The committee evidently agrees with Sir Maurice Craig, who justly considers that "the will to die is the primary matter," and that if it accomplishes its end by adopting an outside suggestion, the suggestion is accidental to its inflexible purpose. That it cannot be deflected is also the opinion of Mr. Ingleby Oddie, who points out that a determined suicide can easily find some way of exit. Still, on the whole, the suicide who does not suffer from a fixed idea will take the easier and more comfortable way. It appears from the report that the rate of suicide among women is now higher than before the war, and that they show distinct preference for coal gas deaths. Certainly women often feel a nervous horror of some method of death like hanging, while of death itself they may have little dread; and gas offers a quiet and unrepelling process of escape. Probably the difficulty of obtaining lethal drugs has increased the number of coal gas suicides. The report cautiously admits, however, that "there may be other factors contributing to an increased suicide rate among females."

[1] H.M. Stationery Office. 1930. 5s.1d. 6d. net.

Production of Gas.

The toxic constituent of coal gas being carbon monoxide, the committee has tried to discover whether it is commercially possible to remove this poison from ordinary coal gas, which contains from 5 to 12 per cent. of it; but finds this improvement cannot be effected without a great increase in the price. Indeed, reduction in price can be obtained only by the admission of more carbon monoxide. Most gas undertakings now mix water gas with coal gas, thereby increasing the proportion of carbon monoxide: and the cheapest gas made for domestic purposes, at present, naturally contains most of this deadly agent. But the gas industry insists that economic and social benefits flow from the employment of water gas: and that its prohibition would lead to complications caused by the enlarged sale of coke. Despite the protests of the gas industry that it has no intention of regularly supplying gas excessively rich in carbon monoxide, the report shows a certain disquiet, which many of its readers (and medical readers in particular) will feel more acutely. In this matter the statements of the gas industry must be considered in the light of the opinion of *disinterested* experts. The committee has found that statistics do show that the danger of accidental death from gas poisoning is greater in districts where the proportion of carbon monoxide is high. Yet it follows the Pearce Committee in refraining from advising limitation, while assenting, in its conclusions, to Professor J. S. Haldane's recommendation that more experiments concerning percentages of carbon monoxide ought to be made. On the subject of limitation the committee admittedly did not obtain all the evidence it invited, so that this appears to be the least satisfactory part of the report.

The question of introducing odours and irritants which would make gas escapes more obvious and suicides more disagreeable was not met by any profitable suggestions. It is plainly very difficult to adopt any method which would not be more intolerable to the ordinary consumers than to those bent upon death. With regard to the Gas (Carbon Monoxide) Order, 1922, the report gravely observes that "witnesses who have appeared before us agree that gas as at present supplied possesses a sufficiently characteristic and penetrating odour."

Distribution of Gas.

The committee heard a certain amount of evidence on the fatalities caused by escapes of gas. These were reassuringly few in number, though they naturally attracted public attention; they were due chiefly to the fracture of mains because of alterations in their beds. The gas industry claims improved methods in construction, and finds that street boxes and ventilators are valuable for detection as well as for ventilation.

Use of Gas by Consumers.

Unthinking consumers make mistakes, due to fatigue or forgetfulness of the risks incidental to the use of gas. Most of those who come to grief absent-mindedly confuse the handling of their taps. Absence of stop-pins, and boiling over of kettles extinguishing the gas, do much harm, and it is better for the gas consumer to possess the sense of smell. Tubes, pipes, and meters are sometimes defective. It is astonishing to find that the hideous and dangerous "sliding chandeliers" are still so dear to some old-fashioned people that they refuse to surrender them. It is shocking to learn from the note "on deaths due to products of combustion" that flueless geysers are still so prevalent in small bathrooms. Incidentally, the committee states that it has examined a number of safety devices, and feels that these might be better known. Many gas undertakings do maintain a voluntary system of inspection, which should be adopted by all.

Conclusions.

The committee's conclusions, briefly expressed, are as follows:

1. The number of deaths by suicide from coal gas has increased alarmingly; but the number of accidental deaths gives no cause for disquiet.

2. The frequency of gas suicide merely indicates a change of means; it is not caused by heightened proportion of carbon

monoxide in household gas, many of the suicides being accomplished by "ordinary" coal gas; no effective check on suicide by gas has yet been discovered which is not too expensive and too inconvenient for the community in general; and, finally, such suicide is really part of the wide problem of suicide as a whole.

3. Because of the economic and social benefits involved there should at present be no limitation of the supply of carbon monoxide in gas.

4. The addition to gas of odours and irritants for warning or deterrent purposes is impracticable and valueless.

5. The question of ventilating the subsoil of streets where gas mains are laid should receive more attention from the gas industry, which should not depend on chance detection of leakages. No definite recommendation is made, however, as the cost might prove prohibitive.

6. Gas should not be allowed to enter houses through holes below the ground surface, if this can be prevented without undue cost.

7. The views of the gas industry as to the depth of cover over gas mains are accepted.

8. The gas undertakings should consider the use of steel mains in spite of their apparently vital objections.

9. *All* gas undertakings should adopt the policy of voluntary inspection and careful examination followed at present by *some*.

10. More skill in preventing mistakes might be exhibited by the designers of gas apparatus.

Recommendations.

The "conclusions" seem timid, and even unexpected, after the first part of the report. The gas industry seems to be very tenderly handled, and the question of cost somewhat overrides the respect for human health and life. That the committee is not entirely satisfied appears in its recommendations, which advise a steady vigilance on the part of the Board of Trade regarding the percentages of carbon monoxide with a view to acquiring powers of limitation; a series of experiments on Professor Haldane's lines; the formation of a central body of representatives of the gas industry and manufacturers of gas apparatus to encourage research towards a non-toxic gas and the perfecting of fittings; conferences between the Board of Trade and this central body; urging of voluntary inspections on all gas undertakings; provision by by-laws against certain dangers, especially flueless geysers; and co-operation of the industry with the police, who should report immediately any sign of gas escape in the streets.

The report should be attentively read by all gas consumers, who will probably come to the conclusion that it may not be so very cheap, after all, to have so much carbon monoxide about their homes. As to the figures concerning gas suicide, these point not merely to early treatment for insanity, as Sir Maurice Craig suggests; they appeal ultimately to the social student, whose business it is to discover why life has become so definitely less desirable to so many.

TESTIMONIAL TO SIR RONALD ROSS.

EIGHTH LIST OF CONTRIBUTORS.

WE now print a further list of those whose donations were received during November, December, and January last in response to the appeal on behalf of the Ross Award Fund printed in the *British Medical Journal* of May 11th, 1929. The total amount in hand at the end of January was £12,967 13*s*. 4*d*. A donation of £2,000 by the Government of India was announced by Sir James Barr, chairman of the Ross Award Fund Committee, in our issue of December 7th, 1929. The list published below does not include anonymous contributors or those whose initials only have been supplied. Donations should be sent to Lloyds Bank, Ltd., 110, High Street, Putney, S.W.15.

November, 1929.—The Government of India, the Government of Rhodesia, Dr. W. O. Bedderd, Mrs. Houlding, Executors of the late William Johnston of Liverpool, Miss Jameson, George Kellatt (Brazil), Miss M. G. Tatham, John M. Lewars (Nigeria), J. T. Millward, *Straits Times* (fifth donation), Ophir Valley Estate, W. Pook, Dr. Laura Rees, Mrs. Thomas, Messrs. Thomas Cumbridge and Moss.

December, 1929, and January, 1930.—Sir Malcolm Watson, M.D., Mrs. Burrows, Blantyre Printing and Publishing Co., Ltd., Nyasaland, Gibraltar Exchange and Commercial Library, Mrs. Gluckstein, Mrs. Waldheim, Mr. and Mrs. Morton May, A. F. G. Kerr, Mrs. W. Pitt-Schenkel, Selangor Coast Club, F. A. Southall, Mr. and Mrs. F. H. Skrine, Misses Sanderson, Mr. Isaac Tooke, Tebrau Rubber Estates, Ltd.

Ireland.

Royal College of Surgeons: Charter Day Dinner.

THE Charter Day dinner of the Royal College of Surgeons in Ireland was attended by the Governor-General of the Free State, Mr. James McNeill. In proposing the toast of "The Governor-General and Prosperity to Ireland," the President, Mr. Andrew Fullerton, C.B., C.M.G., who occupied the chair, referred to the death of his predecessor, Mr. T. E. Gordon, as a surgeon of great learning and skill, who worthily upheld the high traditions of the Dublin Medical School. Although of a modest and retiring disposition, Mr. Gordon, he said, had occupied with distinction positions of great eminence in the profession. While he was professor of surgery at Trinity College he had gained the respect of many generations of students. He was also a man of great culture, devoting much of his spare time to literature, art, music, and the drama. All present at that gathering, whether they came from the North or the South, were genuinely interested in promoting the advancement of their beloved country. The delightful air of friendship which pervaded their assembly was ample proof that they had much in common, and that they were only too glad, perhaps, to forget their differences of creed and politics. Replying to the toast, the Governor-General expressed his satisfaction with the extension and improvement of the hospitals he had seen. He thanked the President and the College for honouring him with an invitation which implied that in their opinion he had sympathy with, and respect for, the services they rendered to the people of Ireland.

Vital Statistics for Northern Ireland.

During the quarter ending December 31st, 1929, 5,858 births were registered in the twenty-seven superintendent registrars' districts in Northern Ireland, this number representing an annual birth rate of 18.7 per 1,000 of the estimated population. The equivalent figure for England and Wales is 15.1, and for Scotland 17.8. The rate in Northern Ireland is 0.4 below the rate for the corresponding quarter of 1928, and 2.6 below the average rate for the fourth quarters of the ten years 1919 to 1928. Deaths registered during the quarter numbered 4,051, or an annual rate of 13 per 1,000. This rate is 1.4 below the rate for the corresponding quarter of 1928, and 1.5 below the average rate for the fourth quarters of the ten years 1919 to 1928. The urban mortality from the principal epidemic diseases recorded during the quarter was equivalent to an annual rate of 0.6 per 1,000 of the population, the death rate from these diseases being 0.4 for the remainder of Northern Ireland.

Proposed Village Settlement for Dublin.

The first steps have been taken at the Peamount Sanatorium, co. Dublin, to establish a settlement on the same lines as those that exist at Papworth, Cambridge; a preliminary announcement of this undertaking appeared in our issue of September 7th, 1929 (p. 474). In the Papworth settlement patients, when cured, are offered work in certain industries. They are paid trade union rates of wages if they happen to be qualified tradesmen; if they are without experience they are trained in some industry, and during training they receive wages. They are housed in bungalows, and when sufficiently cured can bring their families to reside with them. The work is graded, and the men and women who are under medical inspection can work in the conditions that are most favourable to complete recovery. At Papworth, now a village, the workers live under ideal conditions; last year they produced goods to the value of £65,000, which were disposed of in the competitive market. It is hoped to have a similar settlement at Peamount in a short time. The first workshop, the building of which has begun, will be a memorial to the late Sir William Thompson, M.D., to whom not only the Peamount Sanatorium, but also the anti-tuberculosis movement in Ireland, owes so much. Patients who are capable of labour are doing most of the work, and they have benefited much in health. They have completed a garage to house the omnibus which will convey patients to the institution instead of the pony and trap hitherto used for this purpose.

Scotland.

Glasgow Royal Infirmary.

AT the annual meeting of the Glasgow Royal Infirmary on February 10th, with Lord Provost Kelly in the chair, Sir David Wallace (Edinburgh) stated that during the last five years the number of patients attending the Infirmary had increased from 66,000 in 1924 to 120,000 in 1929. The total subscriptions for the past year were exceeded only in 1920. Despite the changes that would be made by the Local Government Act, subscriptions to voluntary hospitals were expected to be maintained or increased. Co-operation and co-ordination between the public health authorities and the voluntary hospitals was necessary; and it was satisfactory that the Act had tried to secure the position of the voluntary hospital. For this purpose Scotland would be divided into five areas, in four of which the teaching schools with their hospitals were of the first importance; the fifth was the North-West of Scotland, with Inverness as its centre. In each of these areas a regional committee had been formed, and a request had been made for the appointment of a small committee in each area to maintain intimate relations with a similar committee formed by the public health authorities within it. This probably meant that the public health authorities, after careful consultation with the voluntary authorities, would determine what was needed for the treatment of the sick in each area. Lord Mackenzie's Departmental Committee had estimated that 3,600 additional beds were required in Scotland, and extended accommodation could be found by using auxiliary hospitals for convalescent patients in close connexion with the general hospitals. Edinburgh, for instance, had three auxiliary hospitals with 230 beds for the convalescent patients who passed through the Royal Infirmary. These auxiliary hospitals cost less to build, and their patients could be treated more cheaply than in the general hospitals. There was the same benefit in the scheme proposed by the Glasgow Royal Infirmary for an annexe at Canniesburn. Dr. James M'Farlane, chairman of the Board of Governors, said that during the period from 1899 to 1929 the number of in-patients had increased from 6,472 to 17,776, and the ordinary expenditure from £34,429 to £113,540. Ordinary contributions had risen from £20,043 to £65,202. The position of voluntary hospitals as healing and training schools was not likely to be affected by the new Act. According to the report for 1929, 17,776 in-patients and 102,188 out-patients, a total of 119,964, were treated—6,218 more than in the previous year. The total ordinary revenue of the Infirmary was £87,640, and the total ordinary expenditure £113,540, which was a deficit of £25,900, compared with £34,363 in 1928. Taking into account legacies, donations, etc., total receipts exceeded expenditure by £579; the three preceding years had showed deficits; £15,565 had been received for endowment purposes; 134 beds and 11 cots were endowed. For the Canniesburn Auxiliary Hospital £42,082 was in hand, and intimation had been received of a residuary legacy which might amount to £10,000. The site for this auxiliary hospital, extending to thirty-one acres, was presented as a gift in 1926.

Physical Education.

A demonstration was given in the Music Hall, Edinburgh, on February 10th, in aid of the Chartered Society of Massage and Medical Gymnastics, under the presidency of Councillor Given, convener of the Edinburgh Public Health Department. In a lecture on the importance of physique and correct posture in relation to physical education, Mr. W. A. Cochrane, F.R.C.S., said that games did not necessarily produce a fully erect attitude, and that a slender build often caused a tendency to droop and relax, so that a person with such a physique had much greater difficulty in maintaining a healthy position than had the broad-backed sthenic type. Care should be taken that the slender type of child developed properly. Very high heels flexed the knees and developed a drooping carriage, which resulted in weakness of the abdominal muscles, flat chest, and round shoulders. Physical education was a mental as well as a physical process; an infant took a long time to learn to stand erect. People of slender build had also to cultivate postural tone in the muscles. Correct posture, he thought, should be taught in schools. A demonstration of Greek dancing, including funeral dances, pyrrhic dances, Bacchanalian dances, and dances expressing the sea, fire, smoke, etc., was given later by Miss Ruby Ginner, principal of the Ginner-Mawer School of Dancing, London. In introducing the dances, Miss Ginner said that revivalists of Greek dancing wished to reinstate dancing among the great dramatic arts, and that it was founded on natural elements, such as walking, running, and leaping.

Milk Feeding Test.

A milk testing experiment, larger than any similar test previously conducted in Scotland, was inaugurated in Hamilton on February 15th, by Mr. Tom Johnston, Parliamentary Under-Secretary of State for Scotland, with the double purpose of testing the value of milk as a *food* for growing children, and of helping to relieve distress in Lanarkshire. From February 17th until the closing of the schools in July, 10,000 children will receive a ration of three-quarters of a pint of Grade A tuberculin-tested milk; 5,000 will receive the milk raw, and the other 5,000 will receive it after pasteurization. Another 10,000 will be used as controls. All the children will be weighed and measured for purposes of comparison. The experiment will probably cost about £9,000, to which the Empire Marketing Board is contributing £5,000 and the Central Advisory Committee of the Miners' Distress Fund £2,000. An increased consumption of milk would benefit agriculture, and surgical tuberculosis might ultimately be eradicated by popularizing tubercle-free milk. The investigation is under the control of the Department of Health for Scotland and the Lanarkshire Education Authority.

Medical Progress and Infectious Diseases.

Under the auspices of the Glasgow Corporation Professor John R. Currie of Glasgow University gave a lecture, on February 11th, entitled "Infection and progress." He said that certain diseases had been extinguished in this country long before medicine had discovered their causes or found specific methods of control. Plague, for example, had disappeared with improvement in living conditions and with the systematic extermination of rats. Malaria in Britain had diminished with agricultural drainage, and leprosy had also practically vanished in this country, probably as a result of better housing conditions. Personal cleanliness had prevented the re-invasion of typhus, and the garage, by displacing the stable, had contributed to reduce typhoid fever. Plenty of fresh air would help to prevent diseases spread by the mouth, and much could be done by medical, combined with social, action.

England and Wales.

Moorfields.

THE annual dinner of past and present students of the Royal London Ophthalmic (Moorfields) Hospital was held at the Langham Hotel on February 13th, with Mr. J. Herbert Fisher in the chair. The dean, Mr. Charles Goulden, presenting his report for 1928–29, said that until the year 1927 the record entry of new students had been reached in 1925, when 121 were admitted. In 1927 134 new students joined the school; these numbers coincided with an increase in the entry for the D.O.M.S. examination, and so were an index of greater interest in the post-graduate study of ophthalmology. The past year marked a return to more normal numbers, and 114 students were admitted, although there were no fewer than 204 students attending the practice of the hospital. During the twelve months ending October, 1929, members of the staff, assisted by Mr. Hume and Mr. Brinkworth, had delivered 428 lectures. Professor Elliot Smith gave a series of lectures on the optic connexions in the brain, and Mr. Traquair on perimetry; these had been well attended, not only by members of the school, but also by others interested in these subjects. One old student had been the first to obtain the M.S. degree in ophthalmology of the University

of London. In the first part of the D.O.M.S. examination of the Conjoint Board 42 of the 107 candidates were students of the school, and of the 60 who were successful 33 had attended the course at the hospital. In the second part 55 of the 76 candidates came from Moorfields, as did 39 of the 51 who were successful. During the past year the school had lost by retirement the services of Sir William Lister. Apart from the help he had given in the way of clinical teaching, he was a generous benefactor. He had equipped the department with apparatus for teaching optics, and presented three Zeiss slit-lamps, so that Moorfields now possessed four Zeiss apparatus, as well as other models, enabling three courses of instruction to be given annually. The out-patients' department was about to be enlarged and reorganized. The lay board had already purchased additional buildings for this purpose, and when alterations had been made there would be much better teaching arrangements, space being gained for laboratories, a library, and study rooms. The dean concluded his report by remarking that Moorfields was about to enter upon a new era with the improved out-patients' department. In the old one the school had earned its great reputation, enabling students to work among clinical material that was probably unrivalled in the world. In practical clinical work and teaching was to be found the genius of British medicine. Among the guests at the dinner were the presidents of the two Royal Colleges and the chairman of the hospital.

Central Midwives Board.

At a meeting of the Central Midwives Board for England and Wales, on February 6th, it was announced that Mrs. Bruce Richmond and Dr. J. S. Fairbairn, representing respectively the Queen's Institute of District Nursing and the Incorporated Midwives' Institute, had been re-elected. Intimation had been received from the Ministry of Health that the Poor Law institutions, which would be transferred to local authorities on April 1st next, in pursuance of Part I of the Local Government Act, 1929, would remain Poor Law institutions, except in so far as they might be appropriated by the local authorities for other purposes. It was decided to suggest, in reply, that many difficulties would be removed if the training of all midwives was made uniform from April 1st next, and that Rule E 27, which excused midwives practising in Poor Law institutions, under certain conditions, from the observance of the Board's rules, should be deleted. The Board further decided to send a copy of a letter, in terms suggested by the London County Council, to training institutions, teachers, and local supervising authorities, with an intimation of the Board's opinion that the use of lysol as an antiseptic should be discontinued by midwives, and that it should be deleted from the list of antiseptics recommended by the Board. The following suggestion of the Standing Committee was adopted:

> That, in view of the recommendation of the Departmental Committee on the Training and Employment of Midwives, in favour of maternity institutions where practical training of pupil midwives is approved, having at least twenty maternity beds, no application for approval of training at an institution at which training has not hitherto been conducted be considered by the Board, unless such institution has at least twenty maternity beds; provided, however, that the Board may consider such an application in respect of an institution with less than twenty maternity beds if there be special circumstances which would render such consideration desirable. Further, that no application from a midwife for approval for the purpose of conducting district training should be considered unless such midwife has at least one hundred cases per annum in her practice.

Dinner of the Hunterian Society.

A festival dinner to commemorate the 202nd anniversary of the birth of John Hunter was held by the Hunterian Society of London, at the May Fair Hotel, on February 13th, with the President, Dr. Ernest Young, in the chair. There was a very large attendance of members and ladies, the guests of honour including the Lord Mayor of London and the Lady Mayoress, Mr. Justice McCardie, the Masters of the Apothecaries' Society and the Cutlers' Company, Sir St Clair Thomson, Past-President of the Royal Society of Medicine, the Medical Director-General of the Navy, Sir Rennell Rodd, M.P. for Marylebone, the Mayor of Paddington, and the Presidents of the Medical Society of London, the Harveian Society, the Medico-Legal Society, the West London Medico-Chirurgical Society, and the Chelsea Clinical Society. After the loyal toasts and the memory of John Hunter had been honoured, the toast of "Prosperity to the Hunterian Society" was proposed by *Lord Riddell*, who was in his best vein, and proved himself once more a diligent reader of the weekly medical journals and a close student of medical affairs. In his reply, the *President recalled* that the Hunterian Society, founded as long ago as 1819, had continued to grow in influence and usefulness since its revival after the war. It now numbered 350 Fellows, whose tastes and interests were well provided for by Dr. Irwin Moore and Mr. W. E. Tanner. Perhaps because the stomach was very near the heart, the dinner meetings had done much to promote the success of the society in recent years. The health of the Lord Mayor and the Corporation of the City of London was proposed by Dr. E. Hopewell-Ash, who expressed gratitude for the frequent use of the Mansion House for the society's meetings. The Lord Mayor, Sir William Waterlow, in his friendly reply, paid a tribute to the wholesome and nourishing qualities of turtle soup, and expressed sympathy with John Hunter's objection to public speaking. The health of the guests and kindred societies was proposed by Mr. Ivor Back and responded to by Sir St Clair Thomson, Sir Henry McCardie, and Surgeon Vice-Admiral Gaskell.

Correspondence.

TRAINING IN MIDWIFERY.

SIR,—I am glad to see that the Master of the Rotunda supports the recommendation of Mr. Donald Roy in your issue of February 1st—namely, that medical students and pupil midwives should receive part of their training together. He tells us that this has always been the custom at the Rotunda. During my active service at Queen Charlotte's Hospital for many years I did the same, and I believe it to be of great value to both students and midwives.

With this object we need consider the clinical teaching only, in the labour rooms and at the bedside as the most important, for the following reasons. In practice the doctor and midwife or nurse have to share responsibility and assist each other; it is therefore essential that the doctor should not only know his own work but everything that the nurse knows; and it is common knowledge that many medical men do not know everything that the nurse knows, especially in the management of babies and some details of nursing the mothers which nurses learn in their daily attendance. The natural result is that the nurse is often consulted on these matters rather than the doctor, and she is led to believe that, as she knows some things better than the doctor, she may assume a position of independence, or even of superiority, in other matters, and may fail to inform him of important matters immediately.

For these reasons the student should be present at the clinical teaching of the nurse, and if the physician questions the nurse as well as the student he and the student will frequently find that the nurse will, from her observation and nursing experience, be able to give correct answers in matters of which the student, with perhaps a far greater book knowledge, knows little or nothing. On the other hand, the nurse, being present during the clinical teaching of the student, will learn that in many matters he has knowledge far beyond hers, and she will be less liable to assume a superiority to which she is not entitled, and the joint training should lead to a better appreciation of each other's work.

There appears to be a tendency at the present time to place the responsibility for infant feeding on specialists appointed for the purpose to the staffs of maternity hospitals. This would imply that the obstetrician is unable to undertake what is, for the most part, a simple and usual duty, though cases arise, as in private practice, for which we are glad to have the best advice obtainable.

The result of handing over the entire infant feeding in this manner will certainly accentuate the widely held opinion that doctors know little about babies, and it would appear to be a wise course if the specialists began their instruction with the seniors, so that they should not know less than their subordinates and pupils.—I am, etc.,

London, S.W., Feb. 16th. WALTER S. A. GRIFFITH.

AN IDEAL OBSTETRICAL SERVICE.

SIR,—In the *Journal* of February 1st (p. 212) Mr. D. W. Roy makes a valuable and useful contribution to the discussion of an ideal obstetrical service in a paper on the training in midwifery of medical students and nurses. It should receive very careful consideration, both because of the breadth of experience behind it and of the sound common sense which informs it. To adapt and modernize existing services is easier, more economical, and, I believe, more efficient than it is to scrap the old and build anew.

The training of practitioners and midwives is, as he says, the root of the problem; improvements here should take precedence of all other changes. The obstetrical training which I and my contemporaries received (and that is not so long ago) was deplorably inadequate, even when it exceeded the requirements laid down by the regulations, as mine did. An inadequate training caused me many unnecessary worries and anxieties, and I have reason to believe that some of my juniors still suffer from a like disability. The joint teaching of students and midwives is sound in theory and works well in practice, to the benefit of both. Teachers ought always to be people who are in close touch with the conditions in which their students will later have to work.

While the provision of adequate training is a first essential, it is not all that readily can be done to improve the obstetric service. I think that we ought to recognize that a good service in one set of conditions may not be a sound one under others. For a rural-urban area the following are the main essentials. They could be modified to suit almost any area.

1. Good houses: to make maternity work less dangerous, and to improve the mothers of the next generation.

2. The elimination of handy-women by the provision of trained home helps. The handy-woman will never be driven from the field (unless by drastic action), for the trained midwife cannot compete with her in her dual capacity of nurse-housekeeper, unless the midwife is willing to do the same work for the same remuneration. The handy-woman gives too good value for her money.

3. Before, during, and after labour we need the combination of home help and midwife, with the doctor (who has seen *all* cases ante-natally) in reserve if required or if "booked" by the patient.

4. A few beds in the local cottage hospital for cases likely to be tedious or of moderate difficulty; cases from bad or overcrowded houses; and cases from houses in outlying inaccessible places. The staff required for these beds would be a whole-time midwife, the patient's own doctor, and a consulting obstetrician who could be called on if required.

5. All cases which on ante-natal examination appear definitely abnormal, *all morbid cases, and all sepsis ought to be sent to* a central obstetric hospital.

6. Provision ought to be made for ante-natal and natal, as well as post-natal, specialist advice and help.

Such a service should be adequate, efficient, and economical. I may add that I write as a general practitioner.—I am, etc.,

Redditch, Feb. 11th. HOWARD E. COLLIER, M.B.

DISINFECTANTS IN MIDWIFERY.

SIR,—Probably every other teacher of midwifery has received the accompanying letter from the Central Midwives Board objecting to the use of lysol by midwives. The reasons are excellent—there are many brands of lysol of varying strength, and some not reliable as a germicide if used in ordinary strength (3j to Oj) in any reasonable time, and others, when used in greater strength, harmful to the doctor's hands and the patient's skin and mucous membrane. What is to be done? Lysol is forbidden, but the Board gives no advice as to what should take its place. It is clear that some authoritative body must give advice, for every midwife or maternity home supplying prospective patients with a list of requisites will have to substitute something for lysol. It must be something reliable, reasonably cheap, harmless to skin and instruments alike, and non-staining, an objection to picric acid, flavine, or iodine. May one hope that the double iodide of mercury and potassium may come into its own again for midwifery?—it was used largely until displaced by lysol. It is an *excellent germicide, can be purchased in tablet form in* small quantities (bottles of 25) reasonably cheap, and it is harmless to instruments unless they are immersed in it for lengthy periods.—I am, etc.,

Ipswich, Feb. 6th. JOHN GUTCH, M.D.

*** Dr. Gutch forwards two documents; one is a communication from the secretary of the Central Midwives Board, headed "Use of lysol as a disinfectant by midwives":

I am directed by the Board to send for your information the enclosed copy of a letter which it has received from the London County Council on the above matter and to say that the Board is of opinion that, owing to the variation in bactericidal power of lysol preparations, the use of lysol as an antiseptic should be discontinued by midwives.

The letter from the clerk of the London County Council runs as follows:

The Council has had under consideration the use of lysol as a disinfectant by midwives. As the Central Midwives Board is probably aware, lysol was produced, prior to the war, by a German firm, but during and since the war a number of firms have put on to the market preparations which are known by the name of lysol.

Midwives are taught in their training schools that lysol should be used for disinfecting the hands in the strength of one teaspoonful to a pint of water, and this instruction appears to be generally followed whatever brand of lysol is used. In view of the varying nature of different lysol preparations, it is evident that this is a most dangerous practice. There is a wide variety in the instructions given with different brands of lysol, the strengths of solution advised varying from one to three teaspoonfuls to the pint of water. It has been brought to the Council's notice that, used in the higher strength, it renders the hands rough and causes smarting to the patient.

In order to determine the bactericidal value of the lysol being sold experiments were made with one of the best-known brands which the midwife is instructed to use in the strength of three teaspoonfuls to the pint, and it was found that it required at least three teaspoonfuls to the pint to kill pathogenic organisms in three minutes, while if absolute efficiency was required (that is, the organisms to be killed in one minute) four teaspoonfuls to the pint should be used. It will be clear, therefore, that if this brand of lysol were to be employed at a strength of one teaspoonful to the pint, as commonly used by midwives, it would be quite inefficient as a disinfectant, and a real danger by giving a sense of false security. It may be mentioned that the instructions in this case were not on the bottle, but on a wrapper enclosed therewith, which most midwives would throw away unread. Further experiments were carried out with one of the cheaper brands of lysol. In this instance the bacteriological results showed that, even if the solution were used at twice the strength recommended by the manufacturers, organisms would live for as long as ten minutes.

The Council is of opinion that these results show a very dangerous position so far as the use of this antiseptic by midwives is concerned. A further dangerous practice arises in that it is possible, according to information given by some midwives, to obtain lysol from bulk in unmarked bottles at some chemists. The Council is also communicating with the Ministry of Health in this regard. I am directed to draw the attention of the Board to these facts, and particularly to (1) the variation in bactericidal power of lysol preparations, and (2) the variety of instructions given for its use.

LEAD POISONING FROM TAP WATER.

SIR,—As the result of the letter on the above subject in the *Journal* of February 1st (p. 216) I have been inundated with letters bearing on different aspects of plumbism. It is impossible to reply to all the communications separately, but perhaps you will be good enough to insert this comment as a general answer to the various points raised.

1. *Is lead poisoning prevalent?* I think it is very much more common, in mild degrees, than people think. Cabot's

remark on pernicious anaemia applies: "The incidence in any community is a good deal a matter of keenness on the part of the practitioners." To what extent total incapacity is attributable to lead can only be hazarded, but certain it is that lead absorption plays an important contributory part in many diseases.

2. *How is the condition contracted from tap water?* With plumbo-solvent waters, especially when the supply is intermittent, lead is dissolved from the cold-water pipes. Where lead pipes are used in hot-water systems of houses the risk of lead poisoning from drinking water from that source is enormously increased. A glass of hot water at night or in the morning, water from the hot-water tap to save time in making tea, or to accelerate the action of an effervescing saline, are not uncommon histories. Soldered kettles are another cause.

3. *Is the incidence of lead poisoning likely to become greater?* My answer to that is very definitely "Yes," unless local authorities prohibit the use of lead pipes in hot-water systems of new houses. The absurd practice (I almost wrote "criminal," but you cannot hang a whole council) of allowing houses to be built with lead pipes leading from the hot-water cylinders in districts in which the water is known to be plumbo-solvent would be extremely humorous if the results were not tragic.

The local authorities, having committed the offence, must minimize their guilt by a definite and permanent warning notice to their victims, and not play the ostrich behind the pious opinions of people who cannot have knowledge of the facts. They can be assisted by medical practitioners if, when prescribing hot water, definite instructions are given that it must not be taken from the hot-water tap.—I am, etc.,

Wigan, Feb. 14th. W. E. COOKE.

CHILD GUIDANCE CLINICS.

SIR,—I have followed with considerable interest the correspondence between Dr. Gillespie and Drs. Noel Burke and Emanuel Miller in the issues of the *Journal* of December 28th, 1929, January 4th and 11th, and am glad that the importance of the work which the child guidance clinics undertake is being recognized by the medical profession in England. I feel that it is a pity at this stage of development that any disagreement should arise. On the other hand, I tremble for the whole future of the movement lest it should be wrecked in its infancy through being misdirected by men untrained for this very special work.

I am in entire agreement with Drs. Burke and Miller in considering the child guidance clinic not primarily as a training centre for the student of general medicine, for to be able to appreciate the work it is necessary to have a wide knowledge of psychiatry and psychology; without that foundation the worker will founder in a morass of incomprehension.

Other objections to incorporating the clinic with the hospital present themselves. Satisfactory contact with any psychopathic patient is difficult enough in any circumstances, and these difficulties are increased when patients are introduced into a class; with the average child satisfactory contact is still more difficult, and, I should say, would be impossible in class work. Attendance at hospital is apt to involve the patient in long waiting periods, surrounded by other patients; this would be extremely undesirable for children.

Another most important point is that the staff of a child guidance clinic is a specialized and extensive one, and its work could not be undertaken by the almonry staff of any hospital without considerable augmentation. A clinic has specially trained social workers, who thoroughly investigate the home conditions—so important in the child's situation; then there is the psychologist, not represented in any hospital, and lastly the psychiatrist. A liaison between hospital and clinic is most necessary, and in my experience here in America this is happily accomplished.

Let us by all means keep a rapport between our hospitals and our child guidance clinics—the student can always attend the conferences at the clinic, for conferences are an essential part of its functioning, and at these he can learn much of the technique of treatment—but do let us leave our child guidance clinics to function as independent units untouched by those problems which make psychiatric work in the very best out-patient departments something of a difficulty.—I am, etc.,

Philadelphia Child Guidance Clinic, Jan. 30th. D. N. HARDCASTLE.

"PHYSIOLOGICAL DILATATION OF THE HEART."

SIR,—Dr. Claude Wilson's article on physiological dilatation of the heart, which was published in the *Journal* of February 1st (p. 189), seems to demand some reply from myself, since I receive mention as an uncompromising opponent of the views which he so ably expounds. I am sorry that this should be said, because I had imagined that my letters to Dr. Wilson had expressed my position sufficiently clearly.

With the majority of his views I am in agreement, though I confess to difficulty in believing that the left ventricle can put out 30 to 40 litres a minute, as Professor A. V. Hill estimates. That the ventricle distends during diastole in order to increase its output during exercise I have never doubted. How much a ventricle can eject each beat I do not pretend to know.

With considerable skill Dr. Wilson has steered round the difficulties which lie about the clinician. He has discussed ventricular output and "physiological dilatation," but he has not ventured to discuss the clinical picture of such events, or even the physics of such changes as must occur.

The content of a sphere varies with the cube of its radius, since any sphere may be described by the formula $\frac{4}{3}\pi R^3$, R being the radius and π $\frac{22}{7}$. The left ventricle contents are not quite a sphere, since its internal shape is more like a blunt-pointed egg, but calculations for the variations of such a figure are complicated, and since we are going to deal with the changes of at least 50 per cent. in volume the divergence from the sphere—the true sphere—may be disregarded, the error involved in calculation being less than 5 per cent. Let us then consider the contents of the ventricle as spherical. As Dr. Wilson says, the "normal" ventricular output per beat is 2½ ounces (67 c.cm.), this is a diastolic content; and so the normal ventricular diastolic diameter is 5 cm. (R = 2.5 cm.) to which we may add 2 cm. for the thickness of the ventricular wall, so that the diameter of the left ventricle, externally, is 2¾ inches (7 cm.). In moderate exercise the ventricular output rises to 5 ounces (150 c.cm.), and the diastolic diameter rises to 3½ inches (8.6 cm. with R = 3.3 cm.). In full exercise (accepting A. V. Hill's figures) the output of the ventricle may reach 200 c.cm. per beat, which gives a diastolic diameter of 3¾ inches (9.3 cm., R = 3.62 cm.).

Here is a very startling fact—a physical fact—that, even when we take extreme figures, the diameter of the left ventricle only enlarges by 1 inch when its diastolic content changes from 2½ ounces to 7 ounces. Even if we suppose that the whole effect of increase in size of the heart is manifested by a movement of the apex towards the left, and if we suppose that each ventricular diameter is increased by 1 inch, making no allowance for the greater thinness of the wall of the more distended ventricle, then we find that the utmost shift of the apex to the left is 2 inches.

Dr. Wilson tells us of a lad whose apex under his hand changed from the mid-axilla to the normal position—on my own chest this is a change of over 5 inches, but let us imagine that it meant 4 inches in Dr. Wilson's patient. This means that at its lowest the diastolic diameter of the ventricle suddenly changed from 4½ inches to 2½ inches; then under exercise that lad's heart must have had a diastolic content of 505 c.cm. [(R = 4.94 cm.)$^3 \times \frac{4}{3} \times \frac{22}{7}$, 16.8 ounces. I regard this as an impossible figure, and this is why I say that I refuse to believe that the heart ever behaves like a concertina.

It seems to me that there must be a much simpler explanation of what Dr. Wilson felt, an explanation which is not only simpler but more reasonable. The boy's heart was beating "too fast for easy counting"; it was forcible, so that the impulse of its beat was conveyed to the whole chest; it could be felt over a very wide area even into the

axilla; and, as Dr. Wilson felt for the apex beat (the furthest left and furthest down of defined pulsation), which was not easy to define, the circulation slowed, the heart force diminished, and a defined localized apex beat became palpable in the normal situation. What was noted was not a change in dilatation, but a change in the force of the heart. After all, even though the heart is "physiologically dilated" in diastole, if it empties itself completely at each systole, its systolic volume is the same at rest as it is at exercise. Professor Hill's figures, incredible as they are, would be even more amazing if we suppose that under the conditions of full exercise the ventricle put out 7 ounces per beat, and even then is not completely emptied. This argument may be carried a little further, for some have suggested that, under resting conditions, the ventricle may not completely empty itself, in which case the fully exercised ventricle should be smaller during systole than the same ventricle under rest conditions.

Cardiac dilatation is often diagnosed as the sequel of a strain or the result of some infection; various physical signs are attributed to the condition, and various symptoms. It is mentioned in all textbooks, and is supposed to be some sort of disability which results from a weakness of the heart. This dilatation presupposes not only the diastolic distension, but a failure to empty completely during systole. I am not referring to the dilatation which occurs as an adaptation of the heart to a valvular defect, nor to a dilatation of the auricles.

If it were true that cardiac failure was accompanied by dilatation, or that dilatation was necessarily a result of cardiac weakness, then progressive cardiac failure and progressive dilatation of the heart would appear together. Dilatation demands greater work for the same output of blood per beat, and cardiac weakness implies a lessened ventricular capacity for work. It is true that a stretched muscle beats more forcibly, but it does more work in so acting, and this greater work is exactly what a failing heart cannot perform. Physiological dilatation would therefore be a physiological disadvantage to a failing heart, and the ventricle which ejects 2 ounces per beat, completely emptying itself, is acting more economically than the ventricle which contains 3 ounces in diastole and only ejects 2 ounces at each systole.

Among the various physical signs ascribed to the dilated heart is a rapid small volume pulse, which seems to suggest that the ventricle cannot be completely emptying itself. I have never seen this condition clinically; I have never seen a strained heart; and therefore (as I think rationally) I say that I do not believe that either dilatation of the heart or the strained heart exists. This is where I join issue with Dr. Claude Wilson.—I am, etc.,

Edgbaston, Feb. 11th. K. DOUGLAS WILKINSON.

HEART SOUNDS: NORMAL AND ABNORMAL.

SIR,—In Dr. Carey Coombs's address (February 8th, p. 229) he tells us that "it is a little disturbing to find how much uncertainty still surrounds the explanation of so simple [*sic*] a physical sign as the systolic murmur," but if he cannot tell us what is the cause of the normal sounds it is hardly advisable to try and dogmatize regarding those that are abnormal. As long as Dr. Coombs is content to accept the prevailing doctrine that the contraction of the heart muscle together with the banging of the extremely delicate valves is responsible for the production of the "heart sounds" so long will he be unable to reduce the uncertainty to which he refers regarding the systolic murmur.

Personally I cannot believe that Dr. Coombs is prepared to subscribe to the belief that a muscle, when it contracts, is capable of producing a noise, notwithstanding the pretty and elaborate though misleading diagram published by Sir Thomas Lewis showing the simultaneous electrocardiogram and heart sound curve from a normal heart. In this diagram the contraction of the heart muscle is represented by the curve PRST, while the heart sound transmitted by means of the microphone is shown in the form of oscillations. By no stretch of the imagination is it possible for the *shortening* muscle to give rise to *equal* oscillations, and the cause must be found elsewhere.

During life the blood fills the entire cavity of the heart, and consequently has no free surface on which to set up surface waves which might possibly give rise to oscillations. It is true that the blood, when passing through the valve orifices, may give rise to eddies, but eddies are hardly the things of which oscillations are made.

As neither the heart muscle nor the blood is able to set up oscillations the only other possible cause of oscillation is the pericardial fluid. This fluid in health is kept at an equal thickness all over the surface of the heart for purposes of lubrication, and with every beat of the heart is tossed to and fro in an even manner, though in disease, when the negative pressure in the pericardium and its dependent suction action tend to disappear, the movements of the fluid are much more irregular.

When there is a pericardial effusion the fluid has no room in which to be tossed about, and consequently there are no waves and no oscillations which can be recorded, although the electro-cardiogram still records the curve due to the muscular contraction. In pericardial effusion no "heart sounds" are heard, although liquids are good conductors of sounds, and an effusion of this sort should be all the more able to transmit sounds, were any produced in and by the contraction of the heart muscle.

As Sir Thomas Lewis agrees that the oscillations recorded are sound waves, and as the pericardial fluid alone is responsible for those oscillations, it follows that the "heart sounds" are really produced by the pericardial fluid. The recognition of this fact is important in connexion with the advice emphasized by Dr. Coombs as to the advisability of examining patients both lying and standing. This advice would be considerably increased in value were he to state what are the concomitants of that change of position. As I pointed out in the *Practitioner* for May, 1929, wherever there is a change of sound accompanying the change of the patient's position, there is also a change in the shape of the cardiogram and of the radiogram. These changes, in my opinion, are due to the diminished control over the movements of the pericardial fluid caused by the disappearance of the negative pressure in cases of heart disease.

I have to apologize for the length of this letter, but in view of the uncertainty emphasized by Dr. Coombs it is most desirable for us to face facts fairly and squarely.—I am, etc.,

Swansea, Feb. 8th. G. ARBOUR STEPHENS.

GASTROSTAXIS FOLLOWING BURNS.

SIR,—Dr. J. D'Ewart of Manchester reported in the *Journal* of February 8th (p. 242) a case of sudden death in a young child following burns; the points he emphasized being: (1) the satisfactory condition of the local lesions; (2) the changes in the gastric mucosa; and the occurrence of (3) persistent twitchings without unconsciousness, followed by sudden death. I would suggest that death was caused by changes occurring in the gastric mucosa bringing about a state of alkalosis or acute tetany, and that the condition might possibly have been averted by the administration of ammonium chloride internally. The following two cases appear to support this view.

Case 1.—On February 27th, 1928, a boy, aged 2½ years, was admitted to hospital with scalds on his feet from hot water. The dorsum of both feet, the front of the ankles, and 2 inches of the right leg were blistered. The loose skin was removed under general anaesthesia and a 1 per cent. picric acid dressing was applied. A good prognosis was given. The local lesions remained healthy, but on February 29th the temperature was 101° F., and the child looked ill. The next day the temperature rose to 104°; convulsions began at 11.30 a.m., from which there was only partial recovery, and death ensued at 3.15 p.m. Before death tetany was diagnosed from very obvious carpal spasms; the stomach contents were washed out, and were very strongly alkaline to litmus. No vomiting had occurred.

Case 2.—On May 29th, 1928, a girl, aged 17 months, was admitted with scalds from hot tea. There were large blebs on both feet and ankles, the whole of the anterior and medial surfaces of the right thigh and the medial surface of the left thigh were blistered, as were both lips of the vulva. Picric acid dressings were applied, as in the first case, a general anaesthetic being

needed on the first and second days. The baby was also given 3-grain doses of ammonium chloride every four hours in dilute solution from the time of admission. Despite a bad prognosis being made, there was an uneventful recovery, the highest temperature being 99.8° on the third day.

Perhaps Dr. D'Ewart may have opportunities of furthering this investigation.—I am, etc.,

J. G. KINGSBURY, M.B., B.S.Lond.

The Downs Hospital for Children, Feb. 10th.

TONSILLECTOMY OR RADIOTHERAPY.

SIR,—I wish to endorse the statements in the *Journal* of Dr. Douglas Webster on February 1st (p. 216), and of Dr. Christopher Kempster on February 8th (p. 262), on the beneficial influence of *x* rays in chronically inflamed and septic tonsils. I have been employing this method of treatment for some years and my results have been very gratifying in adults with chronic septic tonsils, not necessarily enlarged, in whom tonsillectomy is a serious matter.

The crypts open up, discharge their contents, and become dry and flattened; the patient enjoys a freedom from "throats," and a general improvement in health not experienced for years. The treatment is free from risk, as the dosage need only be half or less than half the erythema dose. There is no pain or discomfort in the method, no interruption of work, and no period of convalescence or semi-invalidism necessitating a change of air to recuperate—all most important economic factors. For these reasons I think that the treatment should be more widely known, and at least as much used as it is on the Continent and in America; I think Dr. Webster has done a good service in drawing attention to it.

In my view the satisfactory results in the chronic septic tonsil are due not so much to the selective action of *x* rays on lymphoid tissue as to their beneficial action on inflammatory conditions, both acute and chronic, caused by the various cocci. It used to be held that *x* rays were contraindicated in acute inflammatory conditions, but Holzknecht has shown that this is not so, and that the key to success is very small dosage suitably filtered according to the depth of the lesion. The beneficial effect manifests itself by either rapid spontaneous resorption and retrogression of the local symptoms, or rapid softening and discharge of the inflammatory products. At his clinic in Vienna, besides septic tonsils and such skin inflammations as erysipelas, phlegmon, abscess of the sweat glands, paronychia, furunculosis, etc., he has applied the *x*-ray method successfully to the acute and subacute inflammations of the female generative organs, such as parametritis, salpingitis, and oöphoritis.

As regards simple hypertrophied tonsils in children I have rather discouraged this method of treatment, unless some contraindication to operative treatment existed, because I was of opinion that much larger doses were necessary to obtain the shrinkage of the excessive lymphoid tissue than to clear the septic crypts, and I did not care to submit the skin of a child to such doses. I am interested to note that Dr. Webster finds small doses effective in such types of cases also.—I am, etc.,

T. I. CANDY.

Newport, Monmouthshire, Feb. 8th.

ANAESTHETICS FOR SHORT OPERATIONS.

SIR,—Mr. Marcus Bird and others extol the value of *ethyl chloride, either with or without oxygen*, as an anaesthetic for short operations, teeth extraction, etc. No one apparently uses chloroform for this purpose, and yet, properly used, I believe it to be one of the safest, simplest, and most convenient of anaesthetic agents. There is a strong prejudice against the use of chloroform, resting, I think, upon old tradition, and, except in midwifery, its analgesic properties have been generally ignored. By continuous inhalation of chloroform vapour for from forty to sixty seconds analgesia without loss of consciousness can be produced, and it is possible to remove several teeth without any sensation of pain, although the patient is perfectly conscious of what is being done.

The chloroform may be administered, as I have described *in a previous communication,*[1] *in an ordinary dental chair;* a Skinner mask is placed over the mouth and nose and chloroform dripped *continuously* from a drop-bottle; after from forty to sixty seconds, or possibly a few seconds longer, the mask is removed and the analgesic stage lasts for half a minute or more. There are no unpleasant after-effects, and no post-anaesthetic vomiting. The patient is able to get up at once and walk.

In such operations as incising carbuncles, whitlows, etc., for which nitrous oxide or ethyl chloride is generally used, chloroform may be given as satisfactorily, but the time of induction should be a little longer—up to ninety seconds. It should not be pushed as far as the excitement stage, and consciousness, though perhaps impaired, should not be lost. I believe *chloroform given by this method* to be at least as safe as any other anaesthetic, and certainly more convenient.—I am, etc.,

Ipswich, Feb. 8th. HERBERT H. BROWN.

[1] *Clinical Journal*, December 11th, 1929.

TENNIS AND GOLF ELBOW.

SIR,—As the pathology of these conditions is still a subject of dispute, the report of individual cases which are clear-cut and free from doubt should prove of value.

A few weeks ago, when making an iron shot off a patch of hard, uneven gravel, I experienced a sudden severe pain about the inner condyle of the left humerus. The grip and the timing must have been fairly good, for the ball carried 160 yards; but the shot was pushed out to the offside owing, no doubt, to the toe of the club meeting the hard ground before impact with the ball—a fault which, by giving a twist to the shaft, tends to open out the flexed fingers gripping the club. Throughout the round the same sharp burning pain recurred with about one out of three full shots.

Examination showed no deformity or discoloration, no pain or interference with movements of the joints, but acute tenderness on pressure over the distal aspect of the condyle. Now, after the lapse of five weeks, the pain (subdued in degree) can be elicited deliberately in two ways only: (1) by direct pressure in the region of the condyle; (2) by active flexion of the fingers with the addition of passive pressure applied to the palmar aspect of the second phalanx of the ring finger.

The application of pressure upon the third phalanx of the ring finger, or upon any part of the other flexed fingers, fails to elicit the pain. It is therefore clear that the injury concerns the ring-finger fibres of the flexor sublimis digitorum muscle. That much is certain; the continued tenderness of the tip of the condyle gives me the impression that the periosteum rather than the tendon is damaged.

Any enthusiast on this subject is welcome to examine the culprit, but I will ask him to leave his scalpels behind, as my kind friend Dr. Rolf Creasy has just undertaken some milder measures of treatment.—I am, etc.,

London, Feb. 12th. E. B. WAGGETT.

SIR,—Apropos recent correspondence in your columns the following notes of a case may be of interest in connexion with possible underlying causes of this condition.

For many years painful fibrositic nodules in various parts—shoulders, neck, back, and tendo Achillis—disappearing with massage but reappearing in other parts. Then, when playing golf, sudden onset of tennis elbow symptoms, becoming very acute in two or three days and making golf impossible. Has never played tennis. The most striking physical sign—acute tenderness on percussion on the external condyle of the humerus, just above the radio-humeral joint. Complete recovery in some months with massage, and in the later stages graduated active exercises. When the arm became well enough to warrant golf-playing again the other arm became affected in the same way, and took months to get well.

Given a fibrositic condition of the common tendon of origin of the extensor muscles it is easy to see how damage may be done by swinging a driver or brassie. In the early part of the upstroke the right arm supinates, then the extensor muscles of the right wrist contract to bend the right wrist; after the ball is struck the left arm supinates, then the extensor muscles of the left wrist contract to bend the left wrist. It is not very unlikely that a fibrositic condition of the common tendon is a

predisposing cause of many of these cases of so-called tennis elbow.

In all the cases I have seen acute tenderness on percussion, as distinguished from mere pressure, on the spot mentioned above, has been the most striking as well as the most persistent physical sign. I have never found anything like the same amount of tenderness of the head of the radius or of the radio-humeral joint.—I am, etc.,

Matlock, Feb. 14th. R. MACLELLAND.

PAPILLARY GRANULOMA OF LARYNX AFTER EXPOSURE TO IRRITANT GAS.

SIR,—I have been invited to collate cases of papillary granuloma of the larynx, or of a similar nature, with special reference to occurrence after exposure to mustard or other irritant gas, for presentation at the Summer Meeting of the Laryngological Section of the Royal Society of Medicine. The points of note appear to be:

1. Signs and symptoms, clinical appearances.
2. Date of exposure to gas, nature of latter.
3. Latent period, if any.
4. Operative measures, exact site of granuloma, pathological report.
5. Exclusion of syphilis, tubercle; ? blood or sputum examination.
6. Subsequent history.

I should be very grateful if any of your readers will supply me with notes of cases of this seemingly somewhat rare condition that they have seen: illustrations, microscopic slides, etc., and, of course, personal presentation of notes at the meeting, will be especially welcome. References to published cases, or to occurrence apart from war service, will be valued. Any communication should be addressed to me at the Royal Infirmary, Bristol.—I am, etc.,

Clifton, Feb. 13th. E. WATSON-WILLIAMS.

PSITTACOSIS.

SIR,—In your article on psittacosis in the *Journal of* February 8th you say "One would have thought that coroners investigating recent cases would have pointed the moral of close personal contact between man and his pets, but they do not appear to have seized the opportunity."

From information which I possess, only two inquests on presumed cases of psittacosis have been opened recently, and both have been reported fully in the *Times*, giving the coroner's name in each. One was opened by me on January 23rd last, and adjourned until February 20th. The other by a London coroner, quoted in the *Times* of February 6th, and adjourned until March 4th. From both these reports it is clear that the inquiries were only opened formally to permit issue of the necessary burial order, and adjourned for the attendance of material witnesses, who were themselves suffering from the condition, to recover sufficiently to give evidence, and to give time for the necessary preliminary investigations and the collection of evidence.

It would be manifestly unwise for any coroner in these circumstances to issue advice to the public at such a formal opening and without the proved facts before him, and for this reason I suggest that your remarks quoted above are not fair comment. If such advice is shown to be desirable it can properly be given by the coroner when the inquiry is complete. In the meantime, if circumstances demonstrate a necessity for public enlightenment, that is a matter which rests with the local sanitary authority or the Ministry of Health.—I am, etc.,

W. H. DAVISON,

February 11th. H.M. Coroner, Birmingham.

A FACTORY CLINIC FOR TUBERCULOSIS.

SIR,—The opening early this spring of a factory clinic in the Swiss mountains for certain victims of tuberculosis coincides so nearly with the publication of last year's preliminary vital statistics that one may be forgiven for suggesting that the Ministry of Health might do worse than explore the possibilities of the Swiss idea for adaptation amongst ourselves.

At Leysin, 4,500 feet above sea-level, there is now being completed, under the direction of Europe's most eminent practitioner of sun healing, Dr. Auguste Rollier, a series of open verandah workships several stories high. All the beds are provided with work-tables and special apparatus to allow the patients, who are surgical cases, to work in any position required for their cure. Here in the open sunlight, or, when the cold winds come, behind vita glass windows letting in the natural ultra-violet rays, they will turn out watches, stockings, pottery, speedometers for aeroplanes and motors, and other products, all at the usual industrial rates. I am told that the work for some time to come has already been contracted for.

If we mean to mend the grave situation disclosed by last year's figures for births and deaths, in which the part of the white scourge must have been dire, here surely is an agency full of hope not less from the point of view of prevention than from that of actual cure.—I am, etc.,

House of Commons, Feb. 19th. H. H. LAWRIE.

*** We may recall that Dr. Rollier contributed to our issue of December 28th last (p. 1206) an article on "The sun cure and the work cure in surgical tuberculosis," in which he described his factory clinic at Leysin.—ED., *B.M.J.*

MEMORIAL TO HENRY HILL HICKMAN.

SIR,—An appeal was launched about a year ago to recognize and perpetuate the memory of Henry Hill Hickman, a pioneer in general anaesthesia by inhalation. Thanks to a generous response from individuals and societies, our committee has been able to make the following arrangements. (1) A memorial tablet, designed and executed by Mr. Eric Gill, will be unveiled in Bromfield Parish Church, near Ludlow, on April 5th next, being the centenary anniversary of Hickman's burial. (2) His grave in the churchyard will be restored and the tombstone relettered. (3) A Hickman Memorial Medal with an endowment fund to be awarded for original work in connexion with anaesthesia. In addition, we hope to arrange for a portrait of Hickman to be presented to the Royal Society of Medicine. Finally, Mr. Henry Wellcome has very generously made a collection of memorabilia connected with Hickman. These will be demonstrated at a meeting to be held, probably, on Wednesday, April 2nd, the centenary of Hickman's death.

The names of subscribers and the total amount obtained will shortly be published and the appeal closed. Before doing so the committee invites all those who may have overlooked the matter and who appreciate all that is due to the discovery of general anaesthesia and wish to encourage its development, to send a donation to the honorary treasurer, Mr. V. Warren Low, 76, Harley Street, W.1, before March 1st. The list will be published soon afterwards.—I am, etc.,

CECIL HUGHES,

London, W.1, Feb. 15th. Honorary Secretary.

Obituary.

JOHN WRIGHT MASON, M.B., C.M., D.P.H.,

Late Medical Officer of Health for Kingston-upon-Hull.

WE regret to record the death on February 7th, at Hull, of Dr. J. W. Mason, in his seventy-eighth year. Some months ago he underwent an operation, but did not regain his usual health.

John Wright Mason was born near Grantham, and received his medical education at the University of Aberdeen and Guy's Hospital. In 1875 he graduated M.B., C.M.Aberd., and obtained the diploma M.R.C.S.; he became D.P.H. in 1889. After spending some years in general practice he was appointed medical officer of health for Hull, devoting himself thenceforth to the steadily increasing work connected with the prevention of disease and the promotion of sanitation in an expanding city. He was the author of an account of the sanitary history of Hull, and wrote various articles in public health journals.

We are indebted to Dr. W. ALLEN DALEY, who succeeded Dr. Mason in Hull, for the following tribute.

The passing of Dr. Wright Mason leaves an important blank in the ranks of the pioneers of sanitation in this

country. It is nearly fifty years since he was appointed medical officer of health of Hull—now the city of Kingston-upon-Hull. Under his guidance the department which he controlled grew from almost a single-handed affair to one containing some 600 persons. He took a keen interest in all developments of public health work, though he had misgivings as to the wisdom of some of its more recent advances; his knowledge of infectious diseases and what is now called environmental hygiene was unsurpassed. He had dealt with cholera, plague, and serious small-pox epidemics, and he was responsible for the erection of one of the finest disinfecting and contact stations in the country. His chief loves were, however, medico-legal work and port sanitation. Until a few months of his retirement in 1925 he acted, single-handed, as police surgeon to a force of some 450 men; he took a daily sick parade, and spent much time in visiting sick policemen in their homes. He had a wonderful collection of specimens from cases of medico-legal importance, and an honour which he esteemed highly was that of examiner in forensic medicine in the University of Edinburgh. He was a great authority on port sanitation; he was one of the founders, and for some thirty years the honorary secretary and treasurer, of the Association of Port Sanitary Authorities of the British Isles. He was always too busy to have many hobbies, but he took a great interest in the Volunteer movement, Freemasonry, and the collection of old armour. He resigned his public offices in March, 1925, and was the recipient of many valuable gifts. His wife predeceased him by two years. He lost one son in the war, and is survived by four sons and a married daughter.

The Services.

THE Chadwick gold medal and naval prize of £100 was presented to Surgeon Captain Sheldon Francis Dudley, R.N., on February 13th, prior to the delivery of a Chadwick Trust Lecture by Professor B. Blacklock, on health in West Africa. The award is made under the Chadwick Trust scheme, once in every five years to the medical officer of the Navy, Army, or Air Force who, in the opinion of the Medical Director-General of the particular arm of the service, shall have, in the preceding five years, specially assisted in promoting the health of the arm of the service to which he is attached. Among previous recipients of the distinction have been Sir William Horrocks and Sir Wilfred Beveridge on the Army side, and the late Surgeon Commander Atkinson, who carried out interesting researches and performed a memorable feat of life-saving at the time of an explosion on board H.M.S. *Glatton*.

Universities and Colleges.

UNIVERSITY OF OXFORD.

AT a congregation held on February 15th the following medical degrees were conferred:

B.M.—R. S. B. Pearson, J. K. Marshall.

UNIVERSITY OF LONDON.

THE ceremony of presentation for degrees will take place at the Albert Hall on the afternoon of Wednesday, May 14th. On the evening of the same day the graduation dinner will be held at the Fishmongers' Hall. The Chancellor of the University (Earl Beauchamp) will preside, and the Prime Minister has accepted an invitation to be the principal guest.

A course of four lectures on chemistry of muscle in relation to problems of cellular physiology will be given at University College, Gower Street, W.C.1, by Professor Otto Meyerhof of the Institute of Physiology, Heidelberg, on March 6th, 7th, 10th, and 12th, at 5.15 p.m. At the first lecture Professor A. V. Hill will preside. The lectures, which will be delivered in English and illustrated by lantern slides, are addressed to students of the University and to others interested in the subject; admission is free, without ticket.

Dr. Samson Wright has been recognized as a teacher of the University in physiology at King's College (Faculty of Medicine), and Mr. Reginald Lovell as a teacher of bacteriology and immunology at the London School of Hygiene and Tropical Medicine (Faculty of Medicine).

The subject selected for the Rogers prize essay or dissertation for 1931 will be "Enterable viruses as a cause of disease in man."

Dr. Herbert G. G. Cook has been reappointed the representative on the Court of Governors of the University College of South Wales and Monmouthshire for a further period of five years.

The University medal at the M.D. examination (Branch I, Medicine) for internal and external students, December, 1929, has been awarded to Cyril F. Fernando of University College Hospital.

Applications for grants from the Thomas Smythe Hughes and Beaverbrook Medical Research Funds must be sent in not earlier than May 1st and not later than June 15th, 1930, and must be accompanied by the names and addresses of not more than two persons to whom reference may be made. The grants are allocated annually for the purpose of assisting original medical research. Further particulars can be obtained on application to the Academic Registrar.

UNIVERSITY COLLEGE.

The eighth biennial Sydney Ringer Memorial Lecture will be delivered at University College Hospital Medical School on Monday, March 17th, at 5 p.m., by Professor E. B. Verney, M.B., F.R.C.P., whose subject is "The reserve forces of the kidney." Sir John Rose Bradford, President of the Royal College of Physicians, will take the chair. The lecture is open to all qualified practitioners and medical students.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

In connexion with the course of study for the diploma in public health Dr. W. G. Savage, M.O.H. for the county of Somerset, will give a lecture on food poisoning, at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1, on Thursday, February 27th, at 5 p.m. The lecture is open to the public.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary Council meeting of the Royal College of Surgeons was held on February 13th, when the President, Lord Moynihan, was in the chair.

Diplomas.

The diploma of Fellowship was granted to Mr. G. C. Dorling of the London Hospital, who has now complied with the regulations.

Diplomas of Membership were granted to 136 candidates.*

Diplomas in Public Health were granted jointly with the Royal College of Physicians to 40 candidates.*

Honorary Medal.

The Honorary Medal of the College was awarded to Professor Grafton Elliot Smith for services to the Museum.

Appointments.

Mr. Victor Bonney was re-elected a representative of the College on the Central Midwives Board for one year from March 31st, 1930.

Mr. R. E. Kelly was re-elected a member of the court of the University of Liverpool for three years from January 1st, 1930.

Lectures.

The President reported that he had appointed Sir J. Herbert Fisher as Bradshaw Lecturer for the ensuing year.

The President reported that Sir Arthur Keith's Hunterian Lectures had been postponed to May 5th, 7th, 9th, 12th, 14th, and 16th.

Mackenzie Mackinnon Research Fellowships.

The President reported that at a meeting of the Mackenzie Mackinnon Research Fund Committee on January 23rd last the following Research Fellows were appointed for one year each: T. C. Hunt, B.M., B.Ch.Oxon. (subject of research—duodenal catheterization); G. S. Williamson, M.D.Ed. (subject of research—study of diseases of thyroid, thymus, and lymphatic tissues).

Jubilee of the Ophthalmological Society.

The evening reception at the College in connexion with the jubilee celebrations of the Ophthalmological Society of the United Kingdom will be held on Thursday, April 3rd.

Elections to the Council.

An election of three Fellows into the Council will take place on July 3rd at 11 a.m. in the vacancies occasioned by the retirement in rotation of Mr. R. P. Rowlands, Sir Percy Sargent, and Mr. Victor Bonney. Notice of the election will be given to the Fellows by advertisement and circular on March 7th. The last day for the nomination of candidates will be March 17th, and a voting paper will be sent on April 1st to every Fellow of the College whose name is registered at the College.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

THE monthly meeting of the President and Fellows was held on February 7th. The following candidates, having passed the necessary examination, were duly admitted Members of the College: R. H. J. M. Corbet, S. H. Faulkner.

It was resolved that in the by-laws for the Licences in Medicine and Midwifery and in the by-laws for Membership, the term "registered medical practitioner" shall be interpreted to mean:

A practitioner of the Irish Free State, or of the United Kingdom, or a colonial or a foreign practitioner, who has been registered or enrolled by the Registration Council of the Irish Free State, or by the General Council of Medical Education and Registration of the United Kingdom under the Medical Acts of the Irish Free State and of the United Kingdom respectively.

Miss Alice M. Barry, M.R.C.P.I., took the declaration and signed the Roll of Fellows of the College.

* The names were printed in the report of the comitia of the Royal College of Physicians published in the *Journal* of February 8th, p. 244.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE Mental Treatment Bill was read a second time by the House of Commons, on February 17th, after a full and sympathetic debate, marked by speeches from six medical members of Parliament—the most ample medical contribution ever made to a Parliamentary discussion. The bill has been sent to Standing Committee A, which, having little other work on hand, will soon begin to examine it.

On February 18th the Road Traffic Bill was debated on second reading. During his expository remarks Mr. H. Morrison, the Minister of Transport, referred to voluntary hospitals. He said that, while the bill was in the House of Lords, an amendment was carried with regard to the admitted problem of the voluntary hospitals and patients injured in street accidents. He was sorry that he had not been able to authorize Lord Russell to accept that amendment on behalf of the Government. He was sympathetic with the position of the hospitals, but he was satisfied that this was not the way to solve their financial difficulties. Mr. Morrison predicted that when the House of Commons examined the clause in committee they would find inconsistencies and absurdities in it. The hospitals already had a right to charge for their services and say that they would not treat anyone except for payment unless they were convinced that the patient could not afford to pay. But with all the good will in the world towards the hospitals he felt that there would be technical and legal difficulties if the House tried to graft on to a bill of this kind a matter which ought to be dealt with in a bill about the general problem of the voluntary hospitals as such.

The Charing Cross Bridge Bill was down for discussion on February 19th, and the Rural Amenities Bill on February 21st. Dr. Fremantle and other members concerned at the London refuse "dumps" in rural constituencies met on February 18th, and decided to call for appropriate safeguards in the Rural Amenities Bill.

Mental Treatment Bill.

SECOND READING IN THE COMMONS.

In the House of Commons, on February 17th, Mr. GREENWOOD moved the second reading of the Mental Treatment Bill, which has already passed through the House of Lords. He said that he invited the co-operation of all sides of the House in a measure which did not involve narrow party political considerations. The bill sought to carry into law the less controversial proposals of the report of the Royal Commission on Lunacy appointed five years ago, and to deal particularly with urgently needed reforms. The discussions which took place in the House of Lords led him to believe that essentially the bill could be treated on a non-party basis. In the House of Lords certain amendments were made, and in the House of Commons the Government would be willing to consider sympathetically amendments which would improve the measure and were not inconsistent with its main principles. The main emphasis of the report of the Royal Commission was upon the need of a new conception of mental disorder and its treatment. Emphasis was laid on the view that there should be early treatment, and that mental disease should be viewed much in the same way as physical disease was now viewed. The bill made provision for two categories of people—those who recognized the instability of their condition and realized the desirability of taking early preventive measures, and those who were no longer able to realize their condition and who, nevertheless, might be curable, but who ought to receive treatment different from that of the certified lunatic. At present in England and Wales voluntary boarders could only be received in certain institutions, in licensed houses, and registered hospitals under the Lunacy Act, and only in two public institutions where, as a result of special legislation, it was possible for voluntary boarders to be accommodated—the Maudsley Hospital and the London County Council and City of London Mental Hospital at Dartford. It followed from that that with very few exceptions treatment of the voluntary boarder was available only for people who were fortunate enough to be able to pay the fees for entering into those places. That, obviously, in these days, could not be defended. There were no free beds in the licensed houses; and there were only fourteen of them, with 4,700 beds. The great bulk of the public hospitals were not entitled to take in voluntary boarders, and the result was that a vast number of people for whom treatment as voluntary patients would be desirable were debarred from receiving that treatment. Of the 115,000 places in our mental institutions, none were available for persons who wanted to go in in the first stage. There were places which were only for those people who went in with the badge of the certified lunatic in their possession. The object of the first four clauses of the bill was to make more extended provision for the voluntary boarder, and to provide that such boarders might be received into the other types of public institution whose doors to-day were closed against them.

To get a coherent and logical code with regard to voluntary patients opportunity had been taken to repeal certain of the existing provisions and re-enact and bring them together in the first four clauses. In cases of this kind, although in most instances the individual went in of his own free will, there must be some measure of protection. The real distinction between physical and mental disease—even that distinction might at times be blurred—was that in the case of mental disease the will of the individual did not consciously operate. It was necessary, therefore, to have some measure of protection in the interests of the people who entered these institutions. While provision was made to permit a person of less than adult years to become a voluntary boarder on the application of a parent or guardian, safeguards had been introduced requiring the support of definite medical evidence as to the desirability of the young person undergoing treatment, and provision had been made for the intervention of the central authority if the parent or guardian did not appear to be carrying out his duty after the minor had been placed in the care of the institution. The next problem of the voluntary boarder was as to his release. It was quite clear that if a person voluntarily entered an institution for treatment he could not be permitted to leave exactly when he liked. As the law stood now, a notice of twenty-four hours was required; in the bill it was proposed that seventy-two hours' notice should be given. That was not because anybody desired to retain people against their will, but in order that there should be sufficient time to communicate with the friends or relatives of the patients and make effective arrangements for their care when released. It would be generally agreed, so far, that the Government were going on the right lines in opening more doors for voluntary treatment.

Temporary Treatment Without Certification.

In Clause 5, on which a certain amount of doubt had been expressed, they were dealing with the person who had gone a little too far to appreciate that he was a victim of incipient mental disorder, and who, while not being a resistant type of case which called for certification, ought to receive some method of treatment. The cases he had in mind under Clause 5 were those of the man whose mind had been temporarily broken by overwork, of the woman in childbed who suffered from puerperal mania—cases where, with proper treatment, fairly early recovery might reasonably be expected. To-day, the moment that a person's mind became temporarily unhinged he was not only branded with the stigma of the Poor Law, but with that of certification. The stigma of certification was a real thing, which had kept from proper institutional treatment many people who might well have benefited from it. He was not sure that in many working-class homes to-day the stigma of judicial certification did not stab deeper than that of the Poor Law. It was essential, if they were to do any justice to people who, in the months to come, would be as normal as the rest of their fellows, that something should be done to get for them proper adequate treatment without putting on them the brand of certification. It raised a very large and difficult question. They knew that a substantial proportion of people who entered institutions, duly certified, were people who did recover. In the report of the Royal Commission a number of statistics were quoted in regard to various mental hospitals, which showed that quite a substantial proportion of people who entered the Poor Law mental institutions were released in a relatively short space of time. One of the best instances, because the figures covered four years, was that of the Claybury Mental Hospital, where, out of 792 recoveries of sanity, 11 patients recovered within the first and second months; 49 between the second and third; 71 between the third and the fourth; 76 between the fourth and fifth; and 83 between the fifth and sixth months. In other words, over a fourth of those recoveries took place within six months. It was proposed that, subject to safeguards, these people should be subjected to a period of treatment not exceeding six months. In the case he had quoted, over one-fourth of the people who recovered in that asylum would, under Clause 5, never have had to undergo judicial certification. It was clear that if they had more early treatment of this kind, more cases would recover. Even at the end of six months they were not justified in condemning the patients who still remained to certification. It was therefore provided that there should be a continuance of the treatment for a further period not exceeding six months. Here the Government had departed from the recommendations of the Royal Commission. This was done after very mature consideration. The Royal Commission, being anxious to differentiate cases which should be certified from those which need not be certified in the first instance, cast about for a procedure which would be different from certification. They devised the plan of a provisional treatment order, and they proposed, "with reluctance," that the order should be signed by a magistrate, though it was clear from the general tenor of their report that they would be glad to get away from judicial interference. When the Government came to work out what the provisional treatment order would be, it was clear that, to the ordinary mind, it could not have

been distinguished from ordinary certification. He felt this so strongly that if the principle in Clause 5, as it now stood, was destroyed, the heart would have gone out of the bill. They ought to devise machinery which was distinguishable from certification, and that was the whole point of the clause—to get treatment for the non-volitional case without having to resort to the intervention of the magistrate, with all that that meant. There must, however, be safeguards, and a number had been inserted which would be an adequate protection. First, there must be two medical recommendations to support the application made on behalf of the non-volitional patient, one signed by a medical practitioner specially approved by the State, and the other, if practicable, by the usual medical attendant of the patient. This was a further safeguard, because it meant that these cases could only go to institutions that were in the public eye and under a measure of public control. Arrangements were made in Clause 5 for fairly frequent visitations, and there would be periodical visitation by the authority itself. They had tried sincerely to protect the individual and not to introduce the process commonly associated with entrance to a mental institution. He believed the clause would mark a great advance in the treatment of mental disorder, but he was equally sure that the intervention of the magistrate in these cases would destroy the whole value of the clause. If they condemned these people to certification they would not get the early treatment that was desired, and one of the main purposes of the bill would have been defeated. A large body of public opinion was prepared to support the bill and get rid of what had been called the stigma of judicial interference. In this matter they had the vast majority of the medical profession behind them. Lord Dawson had spoken warmly in support of the bill.

Administrative Provisions.

Other clauses dealt with provisions regarding local authorities. Their powers and duties were enlarged, and they were enabled to do more in the way of facilities for treatment. They were also given power to provide out-patient clinics, to undertake after-care and research. Those powers were subject to the approval of the Board of Control, and were so drawn on the specific recommendation of the Royal Commission. Objection had been taken to making this a new duty, but it was not so much a new duty as the application of an old duty in a different way. Now that they had transferred the boards of guardians and there was to be a new development of health services, if they modified the law as regarded local authorities it was clear that they ought to modify it with regard to the central authority. The Board of Control had a long history, which went back to the forties of the last century. It was now being subjected to criticism. The whole intention of the reorganization, set forth in Clauses 11 to 15, was to re-establish the Board of Control on a new basis with a closer contact with the local authorities and with a procedure and a method of administration assimilated to that now followed in the Ministry of Health. It was proposed to reduce the size of the Board and the number of commissioners, and to give power for the appointment of assistant commissioners and inspectors in order to get some effective central provision and administration and a more effective contact with the local authorities. They also gave to the chairman of the Commission new authority, subject, as was laid down in Clause 12, to the Minister of Health. The whole desire behind this proposed alteration in the Board of Control was to adapt that central machinery to the rapidly developing work within the sphere of the Board of Control—lunacy, mental deficiency, and now the powers and activities under the bill. It was assumed, indeed it had been stated, that the Board of Control was a Star Chamber which was not within the jurisdiction of the House. Nothing could be more untrue. It was important to realize that, while for administrative reasons it was desirable that there should be a board of some kind, that Board was as much within the control of Parliament as any State department. When questions were asked about the Board, they were answered by the Minister of Health. There could not be any more complete control.

Protection of Certifying Practitioner.

Clause 16 referred to the protection of medical practitioners who gave certificates under the Lunacy Acts. The position of the medical practitioner to-day was one of considerable uncertainty; indeed, many of them thought that it was one of very real peril. The Royal Commission recognized that. To-day, if the medical practitioner was made the defendant in a case for wrongful certification, the onus of proof rested upon him to show that he had acted in good faith and with reasonable care. It was clear that they could not completely remove responsibility from the medical man. After all, he had made a decision, and therefore, while they must keep upon him a certain measure of responsibility, it was important that he should have reasonable protection against cases which might be brought, and which might mean his financial or professional ruin, even if the cases did not go against him. The clause followed very closely the proposal made in the Royal Commission's report, which was drafted in detail by the very eminent legal members of the Commission.

A further important point in the later clauses of the bill was the Poor Law aspect of the problem. The Royal Commission desired a complete overhaul of the whole system of lunacy administration. That had not been possible, but it had been decided to dissociate people suffering from mental disorder from the Poor Law. They had in the bill removed the pauper's stigma, and that provision, coupled with the abolition of the boards of guardians, would mark a very great step forward in lunacy administration. Clause 17 provided the same kind of procedure for the poor person in case of sudden insanity or sudden mental disorder as applied to the well-to-do. The proposals of the Royal Commission for the assimilation of procedure would have been admirable if they could have been done. But he was not sure that they could have been done very simply. On the other hand, it would make the bill highly controversial, and his aim was to get a minimum of controvery in regard to the measure. It would also, perhaps, have been advisable to follow the report of the Royal Commission in regard to the licensed houses, but that, too, was a burning question full of deep-seated differences of opinion. These matters, therefore, had been deliberately excluded from a bill designed to meet an urgent need and to revolutionize the public mind in its attitude towards mental disease, and to provide early treatment for that disease. It was also designed to reorganize the administrative machinery so as to make the constructive proposals more readily operative and more successful. In committee every effort would be made to accept amendments which would really improve the measure, provided that they did not interfere with the principles on which it was based.

Opposition Support for the Bill.

Sir KINGSLEY WOOD said that he welcomed the main provisions of the measure, because he thought it represented a saner view of insanity. Provided that opportunities were given for the discussion of certain points, the Opposition hoped to be able to co-operate with the Government in the passage of the bill. Speaking subject to what might be said by the medical members of the House, he thought it might be said that mental illness was not being reduced in this country. The recovery rate was not a particularly good one. There was an increasing number of persons suffering from temporary mental troubles due to the increasing speed and strain of life. He was glad to think that in many respects the old conceptions and unhappy methods concerning mental illness were disappearing, but they died hard. There was still the stigma of lunacy, harking back no doubt to the time when madmen were kept in chains and underground cellars. There were two grave defects in the present system. The first was that the present law undoubtedly placed many obstacles in the way of early diagnosis and early treatment; and the second was that, under present circumstances and the present law, there was very little hope of recovery for many poor people in this country. The poorer patient must have reached the final stage before a mental hospital could receive him. He welcomed the proposals in the bill with regard to the voluntary boarder. It might be possible to remove this class of patient altogether from the jurisdiction of the Board of Control, and by that means dissociate this kind of illness from lunacy. That might very well be discussed in committee. A good deal of importance was attached by eminent lawyers in the House of Lords to the fact that, inasmuch as minors could be detained in homes of that character for a certain period at the request of parents, the Board of Control would cause the homes to be visited by Commissioners, and this afforded some measure of protection. How far that protection was substantial could be considered when the bill was in committee. In Clause 5 provision was made for treatment without certification of persons "temporarily incapable of volition." That was a matter which ought to be carefully considered to see whether every protection was afforded. For the first time an order was to be made without what was called judicial authority. If it were possible, subject to proper safeguards, to avoid certification, it ought to be done. Certification as a lunatic raised real apprehension and dread in the minds of large numbers; and persons who had been so certified, even if they recovered, it followed them for the rest of their lives. He doubted, however, whether, from the point of view of the liberty of the subject, the intervention of a justice of the peace was any protection. The justice of the peace who did his duty seriously in that connexion would be in a most difficult position if he were confronted with certificates signed by competent medical representatives. If regard were had to the reports of the last two tribunals which had been set up by that House to consider the treatment of lunacy, cases of wrongful detention must be of the rarest occurrence, and no wrongful detention was deliberately or systematically practised in institutions. He placed a great deal of confidence in the Board of Control and its operations, and the fact that members of the Board could visit those institutions at any time was a considerable safeguard. He hoped that one result of the measure would be that the superintendents of those institutions would have more time to attend to their proper duties. The provisions of the bill which called for further consideration were those relating

to the medical profession and the local authorities. He had a good deal of sympathy with the plea of many medical men that some further protection should be afforded them in the discharge of their duties under the bill than its provisions provided. Additional responsibilities were placed on local authorities, and he had been asked by the London County Council to put forward on their behalf, and on behalf of other local authorities, a claim for further financial assistance. The bill was on the right lines and the Opposition would be happy to assist in its passage.

Medical Support.

Dr. MORRIS-JONES welcomed the bill. He said that at present the State put insane persons into two classes—the private and the pauper—and from the legislative point of view recognized the great majority of these unfortunate people as paupers. If the bill did nothing but remove that classification it would be justified. He heartily welcomed the clauses dealing with the voluntary boarder, although he said that he would prefer the word "patient," and he hoped that the Minister of Health would see his way to make that change, which, although small, would be a great improvement. Clause 5, which provided for the treatment without certification of persons incapable of volition, was causing more controversy than any other clause in the bill. It was the very crux of the measure, and he welcomed the clause very heartily. In the debates in the House of Lords its main provisions had escaped unharmed, and the few amendments which had been made had very considerably improved the clause. The bill for the first time abolished the judiciary, as it were, in dealing with mental patients. His own view was that the intervention of the magistrate in this case was unnecessary and indeed harmful. In regard to Clause 15, dealing with the power to make rules, he was very glad to hear the assurance of the Minister that he would be responsible to the House of Commons for the Board of Control. Clause 16 dealt with the protection of medical men. He was very reluctant to talk about that clause, but he felt that he ought to say one or two words about it. Medical men at the present time were very seriously perturbed and alarmed; in fact, a large number of them positively refused to certify at present. He assured the House that there was no piece of work or individual work done by a medical man in the whole of his life which he undertook with more responsibility than that of certifying one of his fellow creatures to go to a mental hospital. He would like to see a little more protection than the clause gave, and the Minister should adopt the amendment which had been moved in the House of Lords. They did not ask for protection for the rascal nor for the unscrupulous; they just asked that the medical man who had conscientiously, and to the best of his knowledge and belief, done his duty, should be protected, and that he should not then be liable possibly to be mulcted in heavy damages and be put to very great expense and very considerable anxiety, with possibly the ruin of his reputation at the same time. He welcomed the bill, although it did not deal as fully with the lunacy code as he would have liked, and it left out the very vexed question of licensed houses. As the House knew, there were the same number of licensed houses now as in 1930, and he understood that the Royal Commission was a little bit undecided in regard to that. The question would have to be faced. Either licensed houses were performing a useful function in the community, in which case they ought to have facilities for increasing, or they were detrimental, in which case they ought to be restrained or abolished. He regretted that the Government had not been able to deal with that aspect of the question, as this was the time to carry out the unanimous recommendations of the Royal Commission. The bill changed the whole attitude of the Legislature from that horrible word "detention," associated as it was with all the stigma of lunacy and the echo and clanking of chains, to the words "prevention and treatment," which made certification of an insane person not the first preliminary but the very last resort. The bill gave the poor something of the chances of the wealthy for the first time. It changed the word "pauper" into "rate-aided patient." That was something, and it substituted for the words "lunatic asylum" the words "rate-aided mental hospital." He congratulated Mr. Greenwood on his initiative in bringing the bill forward, and assured him, from his own experience, that he would be inaugurating a new era of hope for those of his fellow creatures who were, or might be, afflicted with mental disorder. It was because he believed that the whole conception and aim of the bill, subject to the necessary safeguards for the protection of the individual, was to ameliorate, prevent, and cure mental ailments, that he very heartily welcomed it.

Dr. Ethel Bentham's Views.

Dr. ETHEL BENTHAM said that the bill was long overdue. One of the difficulties in regard to it was to get the confidence of the public in whatever kind of machinery was adopted. Seven-eighths of the people who had to be certified were treated through the Poor Law, and there was absolute horror of the way in which they were treated. She did not believe them to be badly treated intentionally, but the amount of money spent on them and the circumstances surrounding their reception were such that it was no wonder that people would do almost anything to avoid it. She had seen in a reception ward, into which people were coming, a case of puerperal mania in one corner, a raging drunkard brought in in the middle of the night, two or three people whining in one corner, not meaning anything, but never ceasing their noise, and another person throwing things at the nurse in charge. She did not say that all the reception wards were like that, but the reception was, and had been, a scandal for a long time. The third thing which made people so nervous was the mysterious and awful Board of Control. She had been in general practice for thirty years, and had acted as a magistrate in these cases ever since women magistrates were appointed. Therefore she had considerable knowledge of the subject. When she had been able to get to the Board of Control in the interests of the patient it had been helpful; but it was not very accessible. There was thus every reason why the public were mistrustful. If they could get into their minds the fact that insanity or aberration of intellect was not, in the majority of cases, a thing which should be hidden up like leprosy, and if it was once understood that all those who were dealing with these people—whether doctors, magistrates, or the Board of Control—were trying to do their best but that the circumstances in which they were acting were such that it was very difficult for that best to be done; and if there could be a little more trust in one another, many of the difficulties would be solved without very much trouble. But this must be brought into the open, and it must not be overlooked that while they were trying to secure the liberty of the subject and were seriously concerned that no person should be kept for a moment in an asylum who was not insane, they had also to realize that a patient was in an extremely helpless condition. He needed to be protected, first, against himself or herself, and, in many instances, against his relatives. The relatives were the people from whom the patient most often needed protection. It was very difficult to make sure whether a person was cured or not. The general public could not be sure because, when they visited a patient in an asylum, they found him apparently in the enjoyment of every faculty, and it seemed safe to have him out. In a good many instances the people who looked the most well were possibly the least able to be trusted by themselves. As to the single justice, his only use was that he formed a second opinion. If it was provided that in every case—pauper or otherwise—there should be two medical opinions, the justice was not very much wanted. If certification or treatment depended on the single doctor, the magistrate did fulfil a useful role. Mistakes could be made, and where there was only one medical attendant there ought to be something else, although a non-medical magistrate was at such a disadvantage in the face of medical opinion that two medical certificates would probably be much more valuable. It was necessary that there should be some superintending and controlling body—they could call it the Board of Control, or what they liked—but there must be someone to protect the patients. The Board of Control—a rechristening would probably be useful—must come more into the open, the names of its members must be known, and also its place of abode. It must also be possible for the relatives of the patient to get into direct contact with the Board. That would do a good deal to lessen the public distrust and make it feel that mental disease was no more a thing to be hidden, or ashamed of, than scarlet fever, diphtheria, or anything else. If it was brought out into a common-sense, open discussion, most of its terrors would be taken from it. Three members of the Board of Control were rather too few. It was necessary that there should be at least two doctors—one a man and one a woman—on the Board of Control. She would like to see the Board enlarged to five persons. If that were done, and it was brought into the open, a great many of the difficulties would be lessened.

Sir D. NEWTON said that local authorities welcomed the bill. They did not, however, welcome all its provisions. It was rather too strong a line to take to make it mandatory on local authorities to provide suitable accommodation for temporary patients and not to contribute anything from the national purse towards the cost. He challenged the wisdom of transferring the powers of the Ministry wholly to the Board of Control. The local authorities should have been consulted and given, perhaps, wider powers.

Mr. SOMERVILLE HASTINGS said that all who were interested in the early treatment of mental disease would welcome the bill. There might be two opinions as to the exact status of the Board of Control, but such matters might very well be dealt with during the committee stage. It might be necessary to alter the exact status of the Board of Control, but he felt very strongly that some supervisory authority would always be necessary in dealing with mental disease. There were two considerations in connexion with mental disease which required attention. The first was the question of what was best for the patient; what treatment ought to be given, and what could be done to increase the patient's comfort. Another important point was in regard

to protection of the public, the protection of the patient from himself, and the protection of the good name of the patient's family. To achieve the latter object some form of detention was necessary. He was associated with a hospital which treated early cases of mental disease, and their difficulty was that they had no power of detention at all. Therefore their selection of cases was strictly limited, and they could not forcibly detain patients even when it was in their own interest and when they felt that they ought to be detained. Again, many of those patients suffered from some other medical or surgical ailments that could be recognized after close examination by physicians and surgeons accustomed to deal with those other affections, and when those other conditions were treated the patients very often rapidly recovered. One great point in favour of this bill was that it would allow public money to be spent on the treatment of early cases of mental disease, which was now impossible. He was much interested to hear the Minister of Health say that the stigma of certification was a real thing. There was no question that that was the case, and the stigma of association with the certified was also a real thing. He would like to see further provisions in the bill for the withdrawal of the voluntary boarders and those not capable of volition as far as possible from association with the certified, and for bringing them into closer association with the treatment of ordinary medical and surgical diseases. Although there might be ways in which the bill could be improved in committee, it made a very great advance in providing for the treatment of early mental disease.

Captain GUNSTON congratulated the Minister of Health on introducing the bill, though he wished it had been more far-reaching. The Parliamentary Secretary to the Ministry of Health could congratulate herself on her success in overcoming the age-long difficulty of finding the right treatment of the early mental cases without violating the ancient law of the liberty of the subject. The fact that very few lawyers were present that afternoon to talk about the liberty of the subject showed that they must be satisfied. The problem of compulsion had to be faced, and they were bound, especially in non-volitional cases, to restrict to a certain extent the liberty of the subject. Everyone to-day had to sacrifice some of his liberty. They wanted to see every safeguard necessary put into the bill, but they should not overload the bill with so many safeguards that they could not get the cure that they all wanted for these poor people. References had been made to the stigma of certification, but it had not been pointed out that the stigma not only attached to the person certified, but to his children as well. Dr. Devine, in his evidence before the Royal Commission, said that this was a very serious slur; it was irrational that it should be so, but it was. He also added that he had no hesitation in saying that many people became confirmed neurotics from the fact that their relations had been certified. He (Captain Gunston) congratulated the Government on having taken a step towards removing the stigma from people so afflicted, and from their children.

Mr. LOGAN, speaking as one who had had some experience of Poor Law administration, supported the bill. The passing of the old boards of guardians and the coming in of the public assistance committees was bringing in a new trend of thought and a new system into the management of the affairs of the nation. The Minister of Health should take into consideration the question of segregation. It was impossible to deal with mental cases, whether certifiable or for temporary treatment, unless they were segregated. Without segregation classification would be useless. Provision should be made for classification of cases of senile decay in addition to classification of temporary cases which were not chronic.

Mr. R. RUSSELL, in supporting the bill, said that in committee the whole question of the relationship between the local authorities and the Board of Control would come under serious consideration, and would need some remodelling.

Sir JOHN WITHERS said that on the whole the bill was extremely good. Clauses 1 to 4 were excellent, but he must refer to Clause 5. The certificate of the magistrate had been, on the whole, a great safeguard. Under this bill people could be put away in an asylum or home for a whole year without any legal certificate, and his feeling was that that was a mistake. The fact that the magistrate had signed something that the public did not know anything about could not hurt anyone. It was the fact that they were put into an asylum which attracted public attention and caused scandal and worry and trouble. From the point of view of the persons themselves certification was a protection.

A Medical Criticism.

Dr. FORGAN gladly joined in the chorus of praise of the bill, though he would have to qualify it to some extent by calling attention to one or two defects. He would like to say what great benefit institutional treatment for voluntary boarders and the possibility of after-care treatment could be. The bill did not apply to Scotland, for the very good reason that Scotland had its separate Board of Control, and a member of the Royal Commission had stated that the practice in Scotland showed an enormous advance upon that in England. In Scotland those suffering from mental disorder were treated in a very flexible way, with enormously good results from the point of view of the health of the patient. The percentage of the population certified as insane was almost 20 lower than in England, and the different method of treatment might to some extent be responsible for that. As regarded the defects in the bill, temporary patients were, in the opinion of those who had framed the measure, likely to be treated in the existing Poor Law institutions, and many members of the public would think that there was very little difference between a declaration signed by two doctors and certification if the patient was then removed to an asylum. That emphasized the paramount importance of setting up other institutions for the treatment of early cases. But the most important defect was the very serious additional financial burden which would be placed on local authorities. Temporary patients were an entirely new class of patient. Fresh accommodation would be required for them, and fresh expense would be incurred by the authorities, and, if our method of allowing non-volitional cases to remain for six months without certification was going to be effective at all, it would mean for some years an increase in the number of persons who would receive treatment. New accommodation would be required if the authorities were to put into effect the permissive powers which the bill gave them. He was afraid, if this subsection were to remain permissive, that the great majority of the local authorities would be unable financially to undertake any work at all. The bill, as it stood now, was not going to provide early treatment except for those who were able to pay for it. The history of lunacy reform had been a history of good intentions. In 1881 the Commissioners reported that for forty years their efforts had been directed towards obtaining early treatment. Thus, for almost eighty years, the Commissioners had been attempting to obtain early treatment. The keynote of this bill was early treatment. He hoped it would have a unanimous second reading, and that at a later stage it would be so amended as to make it really capable of bringing about a praiseworthy reform.

Dr. Fremantle's Review.

Dr. FREMANTLE said that they were dealing with those distressing cases which numbered already some 135,000 persons in mental institutions. Of these, it was estimated that about one-third were what were called in the bill non-volitional cases—that was to say, from 40,000 to 50,000 were non-volitional cases. As had been said, the expense and necessity of providing for these people were already met. Therefore the need for new accommodation did not arise in their case, although one naturally hoped that in time better accommodation might be provided for them, as for others. With regard to the non-volitional cases, one of the objects of the bill was to lead those who at present were frightened off from certification to submit themselves to treatment, or to be submitted by those responsible for them. Therefore there would be need for further accommodation. It was well to recognize that there had been some exaggerated enthusiasm about the bill as opening a new era. The treatment of the insane had varied with the conception and knowledge of their condition. The first organic stage in our system for dealing with lunacy might be said to have started with the Elizabethan Poor Law and the institutional arrangements which arose at that time. The process of dealing with the insane then was one of mechanical restraint, and that idea continued until King George III, who was himself a sufferer, was treated under humane conditions by Dr. Addington. He introduced the idea of humane treatment, which, applied in such an exalted sphere, naturally attracted attention. Still, the idea of mechanical restraint held sway in the beginning of the last century, until Charles Reade wrote *Hard Cash* and Cockton wrote *Valentine Vox*. The indignation aroused was such that, finally, the lunacy laws were amended. The great Lord Shaftesbury was responsible, more than anyone else, for the passing of the 1845 Act, known as the Magna Carta of the Insane, and he became one of the first Commissioners in Lunacy. He was so much averse from the introduction of the justice into the business of certification of the insane that when, eventually, the Act was passed, he resigned his Commissionership in protest, and stood for the principle which was being introduced in the bill that day. From that time onwards they had had a conflict between what had been called the static mind of the lawyer on the one hand and the dynamic force of the biologist on the other. It was by disparagement to the legal profession to refer to the static mind of the lawyer, because the law must necessarily deal with concrete and defined facts, and that really created the difficulty in this case. The medical profession had necessarily to look at it from the other side. He (Dr. Fremantle) spoke, not as one who had practised the profession of curative medicine, but from the administrative point of view, the view of the lay authority, and especially of the interests of the community as a whole, and especially from the point of view of prevention as well as of cure. Therefore he again called attention to the position of the medical man in the case, which had been referred to already, so pathetically and intimately, by his professional colleagues. The House should consider the position medical men were in when called on to deal with a case that was, first of all, recognized in a family as one

of difficulty, of violent temper, of a rather changeable and fickle state of mind, and of a person difficult to deal with. Commonly, that person was regarded as not only a nuisance, but as being wilfully responsible for the trouble in the family and the household. The medical man came in, and realized that it was a case where the strain, in one form or another, had been so great as temporarily to derange the mind of the individual. It was a temporary early case, and it would be ridiculous to sign that as a case of certified insanity. It was obvious, from the mere facts of the case, that it arose from the normal incidents of health and ill health in a life—such cases as arose after childbirth, after fevers, confusional cases, and temporary alcoholic or toxic cases. These were different cases that arose and which had to be treated by the medical man, who said, "It is absurd that this person should be signed up as insane." These were the cases which up and down the land at present were not being certified, and never would be certified. Therefore here was a way in which these people could get the expert care, comfort, and treatment that would enable them to tide over the time until they could again resume their normal place in family and public life.

Speaking as a justice of the peace as well as a medical man, he (Dr. Fremantle) knew how difficult it was for individuals to find a justice of the peace when he was required in such a case, or to find one who was able to go into the case. As has been well said already, as a rule the magistrate deferred to the medical man's opinion, and said, "The medical man says so, and obviously I must sign it up." It was true, as the Royal Commission found, that the safeguard of a justice having to certify a case was a very small one compared with the safeguards provided in this bill. They had a man who, it seemed to him, was more qualified to look after the safety of those concerned than a justice of the peace, because it was to be a medical man approved by the Board of Control. In fact, the criticism of this proposal made from the medical profession was that it might start a new specialty—a separate and distinct class of practitioners. Be that as it might, he thought that the Board of Control would obviously approve only men who would take the public point of view, and who would realize their responsibilities in the matter. He wanted the House to sympathize with the ordinary family doctor and help him to get through these delays and difficulties that were so troublesome and tiresome to the patients and their families. The medical man realized equally well the necessity for protecting the personal liberty of the subject. He did not believe that anybody so much as the medical man would be so acute and keen to discover any kind of ill-treatment and mischief that was going on in a case. Till the end of time there would always be cases where the law would be defeated; no law would be perfect, and those who supported this measure so keenly only asked people to recognize that they had put in a safeguard of a medical man approved by the Board of Control in addition to the family doctor as a more efficient person than the judicial authority. In regard to the Board of Control, he agreed with many of the criticisms. It had been suggested that there was a stigma attached to the Board of Control, and that a new body should be formed to deal with these persons. There was no need to have a fresh Board for every class of insane or mentally afflicted persons who were to be treated. It was in order to get rid of the stigma that the Mental Deficiency Bill of 1913 was passed, and that the Lunacy Commission was absorbed in the Board of Control. Some stigma must attach to any body which undertook these functions, because they were concerned with people who might eventually be certified as insane. They must trust the Board of Control, and in committee they could consider the clauses dealing with the Board in order to secure that the Board would have the confidence of the public as being efficient and expert, and at the same time a sensible body to deal with this subject. But unless they gave a salary and position to the Commissioners greater than that already enjoyed by the class of experts from whom the Commissioners were drawn they would not continue to get the right class of experts to give their services who would command the respect of the superintendents of the institutions engaged in the treatment of mental disease. Sir Maurice Craig, in his evidence to the Royal Commission, said that he had seen on the Board of Control a considerable change and progress in methods; his former criticism had passed away, and he believed that there was evidence that they were doing their work well and in a progressive manner. The House must not forget the matters which were naturally left out of the bill and which appeared in the Royal Commission's report. There were two germane matters which did appear in the bill, which were of immense importance to the treatment of the individual before and after treatment in institutions. These were the system of after-care and medical hygiene generally. There were many associations which undertook this voluntary work, which was invaluable. Some power was given for after-care, and in committee they would want to extend the powers given to after-care associations in various ways, because everybody would realize that the real trouble of the temporarily insane began when they got back to their own homes, especially in the poorer homes. Above all, they must remember that they wanted to be able to treat cases as early as possible, with a view to preventing many of the 50,000 people now in mental institutions from having to undergo institutional treatment.

Legal Definitions.

Sir BOYD MERRIMAN said he could not agree with Dr. Morris-Jones that the words "incapable of volition" were the best that could be chosen to define the cases in Clause 5. This clause was the heart of the bill, and he did not in the least want to destroy it. He wanted the clause to be read and worked so as to conform with what he understood was the real object of the bill. The Royal Commission made it a definite recommendation that, on the one hand, it was desirable, in talking about lunacy, without giving any rigid definition of lunacy, to adopt a nomenclature acceptable to modern medical thought; and, on the other hand, it said it thought that a greater uniformity of language ought to be devised than was found in the present Lunacy Act. It also pointed out that there was already in the code a large variety of tests or definitions of people's state of mind. For instance, there was the main definition of a lunatic as a person of unsound mind. There were in various sections differences as wide as this: a person of unsound mind who was incapable of managing himself and his affairs. Another case was that of a person of unsound mind who was incapable of managing his affairs, but capable of managing himself, and was not dangerous to himself or others. In another category was a man of unsound mind, admittedly a lunatic, whose lunacy was in its nature temporary, and would probably soon be removed. That looked like the class of case they were trying to deal with in Clause 5. Again, there was another type of person who, though not found to be a lunatic and not detained as a lunatic, was described as being a person who, through mental infirmity arising from disease or age, was incapable of managing his affairs. With all these definitions no attempt had been made in the bill to introduce more uniformity into the description of people suffering from unsoundness of mind. They had, instead, added the entirely new conception of what were called non-volitional cases—a particular definition of a class which had never been used before in connexion with lunacy. The phrase really defeated the object of the bill, because it was impossible to describe people who were said to be incapable of volition as an intermediate class between voluntary boarders and certifiable lunatics. To him, as a lawyer, incapacity for volition without any limitation at all was indicative of the most complete unsoundness of mind that could be indicated. Absence of volition was the criterion in law for incapacity to contract, to make a will, even, if they liked, to be guilty of a crime. They could not describe anybody as being more unsound in mind than to say that he or she was, in every respect, and without any limitation whatever, incapable of volition. Even people who were admittedly lunatics were not necessarily incapable of volition in all respects; but here they were describing this intermediate class, which was supposed to be short of lunacy, as people who were, without any qualification except in point of time, incapable of volition. There was no limit to it on the face of the words. To talk about removing the stigma of lunacy from people with whom they wanted to deal in this intermediate way and then to describe them as incapable of volition, and to leave it at that, was really a contradiction in terms. Mental incapacity to co-operate in a cure did not necessarily involve mental incapacity with regard to other affairs. This matter could be dealt with perfectly simply, for the purpose of Clause 5, without stigmatizing people as being incapable of volition in all cases, whether for the time being or not, by reversing the wording which was applied to temporary boarders in Clause 1. They might simply describe them as being people who were "incapable of voluntarily submitting themselves to treatment for mental disorder." This would avoid any phrase which made them appear to be more mad than the lunatic himself, and which threw a reflection on the patient and on his capacities in any other respect.

With regard to the protection of medical men, everybody was agreed that it was essential to make it as difficult as possible to attack them in connexion with this procedure. The known reluctance of medical men to certify because of the risks which attached to it was a very serious matter in connexion with lunacy proceedings. There was no half-way house between complete immunity for the medical profession on the one side, which had not been seriously put forward, and their liability to be attacked in cases where there was bad faith or negligence. It was in connexion with the provision of safeguards in the latter class of case that the difficulty arose. There was always the risk that a person might be able to get a case on its legs against the doctor. In addition to the real and substantial safeguard provided of going before the judge, who had to be satisfied not merely that there was an allegation of bad faith or of negligence, but that there was sufficient ground for that allegation, he suggested that there should be a safeguard on the analogy of the safeguards which were provided with reference to poor persons' litigation. Before a poor person was permitted to sue there was an independent committee of investigation. It

should be quite possible, in the present case, and it would be in the interests both of the public and the medical profession, to have a voluntary panel of investigation set up, appointed, if they liked, by the Lord Chancellor and the President of the British Medical Association. There should be some independent body like that to investigate any claim which a person who had been certified desired to bring against a doctor, and to make a report to the judge for the assistance of the judge before he was called on to make up his mind whether the proceedings should go on. That was in one sense a matter of detail, but it was of very vital importance. In the interests of the efficient working of the Lunacy Acts, if the doctors could not be given complete immunity they should, nevertheless, be safeguarded as much as possible.

Reply on behalf of the Government.

Miss SUSAN LAWRENCE said that all the points and objections raised were in essence committee points. If there were any other words which would better express the intentions of Clause 5 the Government would be glad to consider them. With regard to the protection of the medical profession, which was dealt with in Clause 16, if they could deal with that matter more satisfactorily in committee, well and good. She very much doubted, however, whether the intelligence of the committee would be able to deal with it any better than had already been done. As to the money which it was stated the local authorities ought to have in order to discharge their duty, she pointed out that that duty was already upon them. The duties imposed on local authorities were permissive. The bill placed other local authorities in exactly the same position as London. It was true that special Acts of Parliament. The bill gave the Government had many imperfections. the Royal Commission said—and the Board of Control very good, but a highly mysterious body. She (Miss Lawrence) did Dr. Bentham had said that she found the Board was under- not wonder, if they looked at the defects which the Royal Commission found. First, it found that the Board was under- staffed, and that its duties entailed much travelling over the country. The Government proposed to remedy that, and to bring the Board of Control into much closer relations with the Ministry of Health than it had been before. It would be more in the position of a department of the Ministry. The chairman, to be appointed by the Minister of Health, was to be an executive officer—in the position of head of a department—and the House need not be afraid that there was no parliamentary control.

At the conclusion of Miss Lawrence's speech there was some further debate.

Dr. VERNON DAVIES said the case of the voluntary boarder or voluntary patient had not been sufficiently stressed. If in any family a patient was certified, horror, shame, and stigma descended on the whole family, and adolescents might be unable to get married. Families in all classes of life did all they could to hide these cases. A change was needed in the public attitude towards mental illness, which should be regarded just as physical illness was regarded. The House of Commons now had a great opportunity. The Royal Commission had made an advance and the Minister of Health had had the courage to go further. Let the House advance a little more and say it was determined to recognize mental illness in the same way as physical illness. The bill fell short of that idea. Notification of voluntary boarders to the Board of Control spoilt the whole scheme. In the eyes of the public that meant that the case was one of lunacy. Liability to inspection at any time by the Board of Control would arouse the suspicion of insanity and there would be no voluntary patients at all. In no circumstances should these be notified to the Board, with the possible exception of infants. The consequence of the "non-volitional" provision would be that in future every case which was not a voluntary boarder would be called a temporary case. No doctor would commit himself to saying that a patient could not get better in six or twelve months. In his opinion the Board of Control was necessary. Its powers should be increased and it should be made responsible to the House of Commons; but it should not be allowed to have anything to do with voluntary boarders, nor should these be sent to mental hospitals. At present they were received in other hospitals at Cardiff, at Oxford, and at the Middlesex Hospital. The bill gave power to extend that. The safeguards proposed in the bill were worthless, and the remedy advocated by Sir Boyd Merriman was little better. He asked the House to remember that doctors had no desire to see people locked up or certified when not insane.

The bill was read a second time.

A motion by Dr. FREMANTLE to refer the bill to a committee of the whole House was rejected by 172 to 60.

The financial resolution in connexion with the bill passed through committee.

[Owing to the pressure on our columns and the length of the important debate on the second reading of the Mental Treatment Bill, we are compelled to hold over several items of medical interest discussed in Parliament.]

Medical News.

A JOINT meeting of the Medico-Legal Society with the West London Medico-Chirurgical Society will take place at 11, Chandos Street, W.1, on Friday, March 7th, at 8.30 p.m., when Lord Riddell will open a discussion on "The Doctor in the Law Courts"; he will be followed by Sir William Willcox and Dr. F. Temple Grey.

A CHADWICK Public Lecture on infant welfare schemes will be delivered by Dr. Stella Churchill, on March 3rd, at 5.15 p.m., in the lecture hall of the Medical Society of London, 11, Chandos Street, Cavendish Square, W.1. Sir William J. Collins, chairman of the Chadwick Trustees, will preside.

AT a sessional meeting of the Royal Sanitary Institute, to be held on February 28th and March 1st in the Council House, Bristol, there will be discussions on the Local Government Act, 1929 (to be opened by Dr. R. A. Askius, medical officer of health), on slum clearance, and on the inspection of food supplies in Bristol.

THE Fellowship of Medicine announces that Dame Louise McIlroy will give a lantern demonstration, on the management of abnormal labour, in the lecture room of the Medical Society, 11, Chandos Street, Cavendish Square, on February 25th, at 4 p.m. There will be a clinical demonstration at the All Saints' Hospital, Vauxhall Bridge Road, and a demonstration on difficult cases of feeding, by Dr. Eric Pritchard, on February 28th, at 4 p.m., at the Infants Hospital, Vincent Square. These demonstrations are free to medical practitioners. A course in diseases of children will be given at the Childrens' Clinic and other hospitals from February 24th to March 8th, occupying afternoons and some mornings; all branches of the subject will be comprised in demonstrations and lectures, and there will be two special visits to College Farm, Finchley, and Thavies Inn, Holborn. A series of demonstrations on the diagnosis and treatment of diseases of the eye will be given at the Royal Eye Hospital each afternoon, excepting Saturdays and Sundays, from February 24th to March 8th. Special courses will be held in March on diseases of the chest (Brompton Hospital); orthopaedics (Royal National Orthopaedic Hospital); neurology (West End Hospital for Nervous Diseases); venereal diseases (Lock Hospital); medicine, surgery, and gynaecology (Prince of Wales's Waterloo Hospital); and gastro-enterology (Prince of Wales's Hospital). Copies of all syllabuses may be obtained on application to the secretary of the Fellowship, 1, Wimpole Street, W.1.

IN connexion with the eighteenth centenary of Galen's birth (A.D. 130) a small exhibition has been prepared at the Wellcome Historical Medical Museum, 54, Wigmore Street, W.1.

A SUMMER course will be held at Varese from July 10th to the 31st dealing with the pathological physiology and the clinical aspects of circulatory and renal disturbances. In addition to lectures there will be practical demonstrations and facilities for clinical and laboratory work. The fee for medical graduates is 200 lire, and medical students are admitted for half this sum. Information about the course, excursions in connexion with it, and facilities for travel and accommodation in Varese, may be obtained from the Institute di cultura medica, Corso Roma 4, Varese, Italy.

A SPECIAL post-graduate course in neurology and psychiatry will be held in English at Professor Wagner von Jauregg's neuro-psychiatric clinic, Vienna, from June 23rd to July 31st, covering the whole of neurology, psychiatry, and related subjects, such as radiology, ophthalmology, and otology, and allowing time for classes in special subjects. Further details may be obtained from Dr. E. Spiegel, Fallstrasse 3, Vienna I. The class is limited to fifteen, and will only be held if there is a minimum attendance of eight.

THE International Labour Office has issued from 12, Victoria Street, S.W.1, two further brochures in its series "Occupation and Health." The first comprises leaflets Nos. 163 to 168, which deal with chemical trades, food of the industrial worker, sulphuric acid, compressed air work, the fur trade, and the manufacture of horn articles. The second contains leaflets Nos. 169 to 176 upon copper and ecral, fatigue in industry, tumours of occupational origin and occupational cancer, employment of children and young persons, confectioners and pastry-cooks, hair, slate, and silver.

IN 1929, up to the end of October, one-third of all the accidental deaths among the 19 million Metropolitan industrial policy holders in the United States were due to motor accidents. This is the only type of accidental death which is now increasing in the United States.

THE fourth Easter medical tour organized by the Société Médicale du Littoral Méditerranéen will take place on April 12th to 20th. It will include a visit to Nice, Juan-les-Pins, Cannes, Grasse, Vence, Mentone, Bordighera, San-Remo, and Monte-Carlo. A five days' tour from Nice to Corsica will follow immediately. Bastia, the Cap Corse, Corte, Vizzavona, the Calanques de Piana, Ajaccio will be visited. The tours are open to doctors, their families, and medical students. Further particulars may be had from Madame Juppé-Blaise, Federation of the Health Resorts of France, Tavistock House (North), Tavistock Square, W.C.1.

THE Minister of Health received a deputation on February 18th from the British Legion on the subject of village settlements for tuberculous men. The deputation gave an account of the success of the work carried on at the British Legion settlement at Preston Hall, and cited statistics to show that the economic results of the work had been highly encouraging. The deputation urged that further Government assistance should be given for the extension of existing settlements, and also that steps should be taken by the Government in conjunction with local authorities to extend the movement in suitable areas. The Minister said he had taken a keen interest in the village settlement movement, and recognized that Papworth and Preston Hall had blazed the trail. He had already visited Papworth, and hoped to take an early opportunity of seeing Preston Hall. He hoped that local authorities with the greater freedom which they would enjoy under the Local Government Act would devote attention to the subject, and he was making inquiries as to areas in which the development of the settlement scheme might be possible. On the question of Government assistance he reminded the deputation of the existing housing and other grants that were now available.

THE congress of French-speaking physicians of North America will be held at Montreal in the middle of next September, when the subjects for discussion will be physiotherapy in all its aspects and cholecystitis.

A CATALOGUE of drugs used in Chinese pharmacies in Malaya has been published by Mr. David Hooper, LL.D., F.C.S., in the December issue of *The Gardens Bulletin* of the Straits Settlements. The crude medicinal substances described were collected by Mr. I. H. Burkill, late director of gardens in the Straits Settlements. The identification of most of the samples was made at the Royal Botanic Gardens, Kew, and in this way it has been possible to produce for the first time a collection of drugs used by the Chinese in the Malay Peninsula. It is stated by Mr. Hooper that while the Chinese on the whole adhere to the use of drugs of their own country—probably by reason of its proximity—their materia medica has been decidedly influenced by the introduction of local and Indian products. The *Bulletin* may be obtained from the director of the Botanic Gardens, Singapore, price 2 dollars 50 cents.

IN its report for 1928–29 the committee of the Society for the Provision of Birth Control Clinics records a year of satisfactory progress. The number of affiliated centres has been increased to twelve by the opening of a new one at Newcastle-on-Tyne, and the eleven other centres, in London, the provinces, and Scotland, have between them given instruction in contraception to 3,799 women. A number of medical officers of mental hospitals and tuberculosis sanatoriums have referred discharged patients and patients' wives to the centres for advice, and the committee expresses the hope that this practice may in future become more general. The society is represented on the Birth Control Investigation Committee, which is pursuing research on the efficacy of the present contraceptive methods and is seeking a more satisfactory method than any now available. The committee affirms its belief that public opinion is now ripe for a great extension of the society's activities, and states that, given the necessary financial support, it would open a centre in every large town in Great Britain. The thousands of women who have been helped during the past few years represent an infinitesimal portion of those who need help, and the society makes an urgent call, therefore, on the generosity of those who believe that its work should be continued and extended. The treasurer is Mr. Harold Cox, 6, Raymond Buildings, Gray's Inn, W.C.1.

THE following appointments have recently been made in foreign faculties of medicine: Dr. H. Burckhardt of Marburg, professor of surgery at Kiew; Dr. Aubry, professor of clinical medicine at Algiers in succession to the late Professor Ardin-Delthell; Dr. Wätgen, professor of pathology at Halle; Dr. Rudolf Schmidt, occupant of the chair of medicine at Prague, professor of medicine at Vienna in succession to Professor Wenckebach; Dr. Leon Gaston Bela Fornet, professor of internal diseases at Debreczen; and Dr. Victor Müller-Hess, professor of medical jurisprudence in Berlin in succession to Professor Fritz Strassmann.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9961, 9962, 9963,* and *9964* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL, Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediocra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh.*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

BROKEN SLEEP.

"D. S." asks for suggestions for the treatment of sleeplessness in the early morning. He writes: I can sleep till about 3 or 4 o'clock in the morning, but not after that. I have turned 70, and have carried on a fairly large practice for over twenty years in an industrial town, without the aid of car or cycle. Apart from the insomnia, I am quite healthy. I usually go to bed at 10.30 p.m. I have tried bromides and aspirin, without any benefit.

URTICARIA FOLLOWING SERUM ADMINISTRATION.

"C. E." asks whether three or four drops of horse serum inserted into a mastoid sinus, with a view to healing it, could give rise to an attack of urticaria all over the body a few hours later. An alternative suggestion is that the taking of small doses of adrenaline twice a day by the mouth for the past four months was concerned. He would be glad to have advice as regards treatment. He further asks with reference to the same patient: Should an asthmatic subject have an antidiphtheric serum injected in the event of an attack of diphtheria? At what rate should it be injected, and should pituitrin be simultaneously injected to prevent anaphylaxis?

DANISH TREATMENT OF ITCH.

DR. E. BAYLIS ASH (Birmingham), replying to the question of Dr. Douglas Ross in the *Journal* of February 15th (p. 323), writes: In order to ensure the solution of the sublimated sulphur in the KOH, 1 kg. of sublimated sulphur should be dissolved by heating in 2 kg. of 50 per cent. solution of KOH. The full procedure will be found on page 739 of the nineteenth edition of the *Extra Pharmacopoeia* (vol. i).

DR. WILLIAM C. HOFFMAN (Bridge of Allan) writes: I find that it takes at least 3 kg. of 50 per cent. KOH to dissolve 1 kg. of sublimated sulphur in order to obtain a clear solution. This solution, when fresh, is of a brick-red colour, and the process of preparation is a slow one: 1 kg. of sulphur added to 1 kg. of 50 per cent. KOH merely yields a fine orange-yellow suspension.

PRECIPITATE EJACULATION.

"A. D. B." (Wimbledon) writes: I had a similar case to the one described by "N. D." in the *Journal* of February 15th (p. 320), the patient being a man aged 25. Belladonna and bromide therapy, cold douching, sexual abstinence, and testicular hormone injections proved useless. I referred him to a mental analyst, and after a few weeks he began to improve; a complete cure resulted, the general health being also much improved.

"E. A. B." (London, W.) writes: In reply to the query of "N. D." I would suggest that the symptom may be psychogenetic. The condition is often successfully treated by psychotherapeutic methods.

PRURITUS.

DR. D. YELLOWLEES (Glasgow) writes: Dr. W. H. Davies's inquiry under the above heading (February 15th, p. 322) reminds me of a case of intractable generalized pruritus in a married lady, who was referred to me a few years ago. The condition cleared up completely after a short and comparatively superficial psychological analysis, with no other treatment. To put it in a nutshell, the lady was "itching" to have a baby. She was one of those people, more numerous—and more "normal"—than is

generally recognized, who unconsciously translate into bodily symptoms the emotional states represented by such phrases as "*aching* for an opportunity," "*gasping* for a chance," "*sick* of this job," and so on. The fact that in Dr. Davies's case the pruritus is associated with impotence strengthens the probability that psychological factors are active, as impotence is, in the great majority of cases, a purely psycho-neurotic symptom. (So also is premature ejaculation, referred to by "N. D." in his query in the same issue of the *Journal*.)

GLASS PERMEABLE TO ULTRA-VIOLET RAYS.

DR. JOHN N. DYSON (Southport), in reply to the inquiry (February 15th, p. 320) by "Forty Years a Subscriber," writes: Vita glass and similar substances allow about 76 per cent. of ultra-violet rays to pass through them. In a town the smoky atmosphere effectually cuts off all ultra-violet rays. In the winter, even when the sun is shining, the minute particles of water in the damp atmosphere of our island have the same effect. It is therefore obvious that in towns and in the winter—the very places and the time when the rays are most needed—there are few, if any, to pass through even a permeable glass. A further consideration, which is generally ignored, is the following: ultra-violet rays cannot pass through even the very thinniest piece of clothing. (A lamp giving out rays twelve and a half times as powerful as those from the sun itself will not affect the skin of the body if a piece of tissue paper is placed on the skin.) A person dressed, or covered in any way, could not possibly receive ultra-violet rays through vita glass (even if these rays were present). The skin of the face and hands, through continuous exposure, is practically immune. A consideration of these simple facts should enable anyone to judge the amount of benefit likely to be obtained by the use of glass of this type.

MR. G. L. PILKINGTON (St. Helens) writes on behalf of the Vita Glass Marketing Board: We were interested to read your reply to "Forty Years a Subscriber" in the *Journal* of February 15th (p. 320). In the main we are in agreement with the substance of the reply, but there are one or two points which are not in agreement with data in our possession. In regard to the frequency with which the windows are cleaned, our researches here have shown that the effect of a film of dust on the transmission of ultra-violet radiation has, in the past, been greatly exaggerated. Our conclusion, briefly, is that dust does not exert a selective absorptive effect on the shorter ultra-violet rays, but that the absorption is roughly the same for any part of the visible and ultra-violet portion of the solar spectrum. It therefore follows that the amount of visible light entering through a window is a fair index of the amount of the ultra-violet radiation entering also.

INCOME TAX.

Appointment: Motor Expenses.

"J. K." holds a county council appointment and receives in respect of the travelling expenses of himself and a nurse an allowance at "5½d. per mile, which roughly covers running expenses." Can he claim anything in respect of depreciation of the car, which works out at about £25 per annum?

*** He can claim only in respect of expenses incurred wholly, exclusively, and necessarily in the performance of the duties of his office, and only to the extent to which they cannot be met out of (unassessed) grants made by his council to meet them. It is not possible to press successfully the view that the council's mileage allowance is for running expenses only, unless he can produce evidence from the council that they excluded depreciation when calculating the mileage rate. We assume that such evidence is unobtainable. Consequently it reduces itself to whether "J. K." can prove that he has spent, within the restrictions stated above, sums in excess of the council's grant. If he can do so he should succeed, but as this in effect would seem to be an attack on the adequacy of the grant, he has obvious difficulties to overcome.

Cash Basis.

"J." purchased a quarter share in a practice as from January, 1928; in the following October his partner died and he bought the remaining three-quarters of the practice. For 1929-30 he was assessed on the basis of the whole of the cash receipts for 1928. In 1929 accounts were issued half-yearly, instead of yearly, as in previous years, and the result was to inflate the cash receipts of 1929, of which a substantial portion went to the executors of his previous partner. What should he do in connexion with the rendering of the accounts for 1929?

*** The only suggestion we can make is that for the purpose of the 1930-31 return the account for 1929 should be rendered on the basis of the value of the bookings, instead of on the cash receipts. If that is done, however, the same course will have to be adopted in future years. The assessment for 1929-30 was correctly made on the whole of the cash receipts for 1928 (though again the "value of bookings" basis might have suited "J." better), and we see no escape from an inflation of the 1930-31 assessment, unless the cash basis be discarded altogether.

"Child Allowance."

"SANTOR" has a son who is an articled clerk to a firm of solicitors; he receives no salary, and is attending lectures, etc., at a law school. Is he entitled to the "child allowance"?

*** We fear the facts do not justify the claim, which in effect must be that the son is receiving full-time instruction at an educational establishment. There is no judicial decision on the facts stated, but a case which was heard within recent years on somewhat different facts does not lend support to the claim.

LETTERS, NOTES, ETC.

EPIDEMIC ENCEPHALITIS AND ITS LITERATURE.

IT should have been mentioned in the footnote to our leading article on epidemic encephalitis and its literature in last week's issue (p. 295) that the report of the Matheson Commission can be obtained in England from Messrs. H. Milford, Oxford University Press, at the price of 15s. net.

ANTIMALARIAL MEASURES IN EAST AFRICA.

THE EDITOR of *East Africa*, in the course of a letter on this subject, writes: May I crave the courtesy of your columns to reply to your criticism of my comments on Lieut.-Colonel S. P. James's report on antimalarial measures in Kenya and Uganda? I did not, and do not, desire to underestimate the value of "real screening," as you call it, but, writing from personal experience of not a few screened bungalows in East Africa, I pointed out that screening is no safeguard against the presence of mosquitos, citing Colonel James himself as showing that screening is in practice often merely a trap for the insects. My opinion, though that of a mere layman, is, I find, exactly that of Professor W. S. Paton and Dr. A. M. Evans of the Liverpool School of Tropical Medicine. In commenting on the screening of only a portion of a verandah you write: "In practice this generally means regular exposure to the dangerous anopheles and protection against the merely annoying culicine." It is obviously easier and cheaper to screen effectively a small portion of a verandah than a whole house, and this is commonly done in East Africa. To such a screened verandah many a dweller in the tropics retires on returning from the afternoon exercise to protect himself from the "dangerous anopheles," which gets busy about sunset, and in practice, as I can confirm from my own experience, he finds the protection effective. I cannot agree that culicines are "merely annoying." Paton and Evans say that "in many tropical countries the most troublesome culicines are those concerned in the transmission of the parasites of yellow fever, dengue, and the filariidae." Finally, in attributing to me the "spurious wisdom" of advocating the "positive advantage" of inflicting on new settlers old-time and now avoidable hardships, and of arguing that antimosquito measures are futile, you entirely omit my emphasis that the settler should pay attention to drainage, water supply, quinine prophylaxis, mosquito curtains, and mosquito boots.

MENTAL DISORDER AND INTESTINAL SEPSIS.

DR. W. J. YOUNG (Harston, Cambridge) writes: In this, as in so many things, Voltaire has shown himself that worst of plagiarists, the man who steals our ideas beforehand. The passage is too long to quote, and Voltaire cannot very successfully be condensed, but in his novel, *Lord Chesterfield's Ears*, the great anatomist Sidrac introduces the argument, backed up by evidence from physiology and from history, that the most powerful spring of human action is "la chaise percée." He tells, with peculiar glee, how the emanations from the dried-up contents of an overloaded bowel pass into and poison the whole system, so as to make the merely melancholic man ferocious. He illustrates his thesis with the tale that Cromwell had not visited his "wardrobe" for a week before he cut off the king's head; that the Duc de Guise and his brother were assassinated because they had vexed Henri III when he was extremely constipated; that the massacre of St. Bartholomew was due to the desiccated temperament of Charles IX, "the most constipated man in his kingdom." The anatomist goes on to state that, on the other hand, too great looseness of the bowels sapt the vitality, and that consequently he finds himself unable to credit the legend that the English won the battle of Agincourt when they were suffering so much from dysentery that they fought "with their breeches down," and so had to face the enemy rather than offend the French dandies by turning to them the "*cu-nu*."

CORRIGENDUM.

IN the report of the discussion on intrathoracic tumours in the *Journal* of February 15th (p. 285), the name of Mr. A. Dickson Wright was inaccurately given as Mr. W. H. White.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 46, 47, 48, 49, 52, 53, 54, 55, and 56 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 50 and 54.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 63.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

179. Relapsing Fever.

G. DELAMARE (*Rev. de Med.*, No. 7, 1929, p. 693) records his observations on 50 cases of relapsing fever seen at Constantinople in 1920-21. Most of the patients were Russian refugees; 47 were males and 3 were females. The ages ranged from 10 to 42, the majority of the patients being between 20 and 32 years. The total number of febrile paroxysms was 68, of which 36 were first attacks, 20 second, 11 third, and 1 a fourth attack. The duration of 16 attacks left untreated ranged from three to eight days, and of 52 attacks treated by salvarsan from one to eight days, being usually five days for the first attack, three or four days for the second, two or three days for the third, and not more than forty-eight hours for the fourth. The first relapse occurred between the tenth and nineteenth days, and most frequently between the eleventh and thirteenth; the second between the twentieth and thirty-sixth, and by preference from the twenty-fifth to the twenty-seventh; and the third was on the forty-second day. On examination of the abdomen thirty patients showed a deeply seated and definitely circumscribed tender area, which in 21 was situated in the centre of the epigastrium, in 7 over the gall-bladder, and in 2 over the appendix. In 3 cases epigastric tenderness was associated with tenderness over the gall-bladder, and in 2 there was a coexistence of gall-bladder and appendix tenderness. The complications were as follows. During the attacks: parotitis followed by orchitis, 1 case; albuminuria, 10 cases; haemoglobinuria, 1 case; respiratory complications, 7 cases; meningitis, 2 cases; acute delirium, 2 cases; periostitis, 1 case. During apyrexia: epistaxis, 1 case; visual disturbance, 2 cases; joint symptoms (arthritis or merely arthralgia), 17 cases. One of the most remarkable features of relapsing fever, as observed at Constantinople, was that several cases proved refractory to treatment by salvarsan.

180. The Sympathetic Nervous System and Cardiac Murmurs.

A. VAN BOGAERT and J. MAGE (*Ann. de Méd.*, December, 1929, p. 454) have noted in certain cases, without myocardial insufficiency and previous or present endocardial infection, cardio-vascular signs which might have been mistaken for valvular affections of the heart. They consisted of murmurs at the base of the heart, which persisted most frequently throughout the systole, though sometimes they were diastolic. The authors state that such a murmur is heard with maximum intensity in the second left intercostal space behind the left hemisternum; it is conducted laterally, reaching the clavicles and being audible in the carotids. Occasionally it can be heard, but only faintly, at the base, and it is not conducted to the axilla. With the murmur occurs a bruit, which seems to arise under the auricle, and resembles the dry crepitation produced by the opening of the pulmonary alveoli; the authors term this a crepitant alveolar bruit. These cardiac murmurs originate, they assert, in the aorta, and are conducted as are organic murmurs arising in this vessel, but the clinical picture is that of a sympathetic disorder rather than of a cardiopathy. Their presence is due to an increase of the differential tension (the difference between the systolic and diastolic pressures), and especially to a lowering of the diastolic pressure, the systolic remaining normal or being increased. All causes which produce a return to normal of the lowered diastolic pressure check or attenuate these murmurs. Vascular hypotony and, consequently, ortho-sympathetic hypotony and hypo-excitability (favoured by the relative predominance of the parasympathetic system) cause this condition. Three cases, in which these murmurs were marked, are reported. In two the sympathetic disturbance of the equilibrium could be attributed to endocrine disorders, and in the third to a functional mesocephalic affection.

181. Antityphoid Inoculation in Children.

ACCORDING to J. HESSE (*Arch. de Med. des Enf.*, December, 1929, p. 769), in view of the greater frequency of enteric fever in children as well as in women, as compared with men since the war, and their much milder reaction to inoculation, subcutaneous T.A.B. inoculation should be administered to all children after their third or fourth year. This prophylactic method may be performed simultaneously with the injection of Ramon's anatoxin against diphtheria. It is still more important to inoculate children in the environment of an enteric patient and those living in an infected area, or during an epidemic of the disease. Inoculation should not be performed, at least by the subcutaneous route, in the case of children whose general condition is unsatisfactory, or who are suffering from an acute infection, or cardiac, renal, or hepatic insufficiency. In borderline cases it is best to give the vaccine by the mouth, since this method does not provoke severe reactions. Although the immunity conferred often exceeds two years, it is prudent to carry out re-inoculation by the mouth or subcutaneously every two years, especially as vaccination by the mouth does not render the subject hypersensitive.

182. Post-vaccinal Eruptions.

J. NIEUWENHUYSE (*Nederl. Tijdschr. v. Geneesk.*, December 21st, 1929, p. 5393), who records an illustrative case, states that post-vaccinal eruptions usually appear from eight to twelve days after vaccination or revaccination, and sometimes sooner. A great variety of eruptive forms may occur, such as the amaculo-papulo-erythemato-exudative form, a vesicular form, and very rarely a pemphigoid or haemorrhagic form. The eruption sometimes starts in the neighbourhood of the vaccination and extends therefrom over the arms and trunk, while in other cases it begins on the face. On the face and back it shows a tendency to become confluent. Children with a sensitive skin are predisposed to post-vaccinal eruptions. The season is also important, as most cases were found in the hot summer months. Nieuwenhuyse's patient was a man, aged 52, who had been previously vaccinated at the age of 5; three weeks after revaccination he developed a polymorphous pruriginous eruption on the face, including the ears, lips, eyelids, neck, backs of the hands, and wrists. There was no rise of temperature, headache, or backache. The eruption lasted about a fortnight and then disappeared, leaving some staining.

183. Remission of Encephalomyelitis following Measles.

R. HÜRTHLE (*Deut. med. Woch.*, November 15th, 1929, p. 1922) records the case of a man, aged 49, suffering from disseminated encephalomyelitis, who, after an attack of measles complicated by pneumonia, showed a remarkable remission of all his symptoms, though recovery was not complete. Hürthle regards the improvement as a consequence of the attack of measles, and not merely as a coincidence, or analogous with the improvement in general paralysis as the result of malarial therapy.

Surgery.

184. Supernumerary Kidney.

H. L. KRETSCHMER (*Surg., Gynecol. and Obstet.*, December, 1929, p. 818), who records a personal case and has collected 29 others from the literature, states that true supernumerary kidney is generally regarded as the rarest of congenital renal anomalies. The first case on record was described by Martins in 1656. Of the 30 cases, 21 were clinical, 8 were discovered at necropsy, and in one the type was not mentioned. Of the clinical cases, two patients died after operation, one in eight days and the other in two months. The youngest patient was aged 9 months and the oldest 67 years. The largest number of cases occurred in the second decade of life; 15 were in females, 14 in males, and in one the sex was not stated. In 17 the left side was affected, in 12 the right side, and in one the side was not stated. In most of the cases the supernumerary organ was found below the normal kidney. In 11 cases the supernumerary ureter fused with the normal ureter, in 8 the ureters remained separate, in 7 the course of the ureters was not determined, and in the rest the ureter of the supernumerary kidney was lacking or ended in a blind sac. In 19 cases the supernumerary kidney, and in 10 the other kidney of the affected side, showed various lesions such as stone, pyonephrosis, or hydronephrosis, or was rudimentary. The symptoms were not characteristic; in 16 cases pain was present, other symptoms being nausea, vomiting, frequency of micturition, strangury, and pain in the bladder. A palpable tumour was found in 14 cases, no tumour was present in 6, and this point was not mentioned in 9 cases. Diagnosis before operation was made in only 4 cases. Nephrectomy of the supernumerary kidney was performed in 10 cases, nephrotomy of the supernumerary kidney and the kidney on the corresponding side in 2, nephrectomy in 1, pyelotomy in 1, nephropexy of both left kidneys in 1, nephropexy and

nephrectomy in 1, exploration only in 1, removal of tumour in 1, and no operation in 11. In one case the condition was found accidentally during an operation for ptosed colon. Kretschmer's patient was a woman, aged 22, whose symptoms started one week before operation with severe pain in the right renal region, nausea, vomiting, chills, and fever. A palpable tumour was present. At operation the supernumerary kidney, which showed infected hydronephrosis with dilatation of the ureter, was found behind the right kidney. The supernumerary ureter was fused with the other ureter outside the bladder. Nephrectomy of both right kidneys was performed and recovery took place.

185. Classification of Tumours.

D. A. WELSH (*Journ. Cancer Research Committee, University of Sydney*, November 1st, 1929, p. 167) discusses the principles of classifying new growths, and distinguishes four essential bases—namely, biological, histological, developmental, and regional. The biological basis separates the relatively innocent from the relatively malignant types, and for practical purposes this basis may be associated with a morphological one, which differentiates the epithelial, endothelial, and connective tissue types. The relation of epithelial and connective tissue new growths to the primitive layers of the embryo affords further assistance in classification, and from this and other considerations the author concludes by recognizing five main groups of tumour growths—namely, the connective tissue, epithelial, endothelial, haemopoietic tissue, and embryonic tumours. The last group includes such diverse types as papilloma and carcinoma of the trophoblast; blastocytoma and neuroblastoma; mixed tumours of the parotid and testis; teratomas of the genital glands; and tumours derived from developmental inclusions and abnormalities. Malignancy may develop in any one of these groups.

186. Torsion of the Great Omentum.

K. SCHWANK (*Münch. med. Woch.*, December 13th, 1929, p. 2095), who records an illustrative case of torsion of the great omentum, states that in most cases inguinal hernia is the cause of the condition. According to Lejars three varieties of omental torsion may be distinguished: (1) torsion in irreducible hernia; (2) torsion with an empty hernial sac after the hernia has been reduced; and (3) pure abdominal torsion without hernia. Most collected 146 cases of omental torsion associated with hernia and 19 cases of abdominal torsion only. To the latter must be added cases reported by Trojan and Schröder, as well as Schwank's case, so that there are now 22 examples of pure abdominal omental torsion on record. Their occurrence is very difficult to explain, but probably in the present case pregnancy was a factor. The diagnosis of torsion of the omentum is very difficult, the condition being usually first mistaken for acute appendicitis or cholecystitis, and the true state of affairs is not revealed until operation, which is the only possible treatment. Schwank's patient was a woman, aged 25, who developed severe pain in the right iliac region in the sixth month of pregnancy. A diagnosis of acute appendicitis or torsion of the right ovary was made and laparotomy was performed. An infarct of the omentum was found and part of the omentum measuring 15 cm. long by 5 cm. broad was resected. The patient made a rapid recovery and went to full term.

187. Congenital Malformation of Ileo-caecal Valve.

P. BOHÈME and M. RIVALLAND (*Rev. de Chir.*, No. 7, 1929, p. 455), who record six illustrative cases, including one which came under their own observation, state that congenital malformations of the ileo-caecal valve are extremely rare, and consist in atresia, a more or less tight stricture, or an absence of one of the segments. The functional consequence of these malformations is the production of a more or less complete intestinal occlusion, giving rise to a severe syndrome, from which the newborn infant rarely survives. When the stenosis is complete the child appears to be healthy at birth, but passes little or no meconium, and usually it is not till the second day that the symptoms of crying, restlessness, and vomiting develop. The abdomen becomes more or less distended, the pulse weak and rapid, the temperature subnormal, and in 95 per cent. of the cases death occurs on the fifth day, though some children may survive for a fortnight or three weeks. When the stenosis is not complete the symptoms are much less pronounced, and consist merely in indigestion and chronic constipation. The condition must be diagnosed from diaphragmatic hernia, intussusception, Hirschsprung's disease, and volvulus. The prognosis is very bad. Of 71 cases in which an operation was performed only one patient (reported by Fockens) survived; in this patient a side-to-side anastomosis was performed. The present authors' patient was a boy, aged 2½ years, who had suffered from constipation and indigestion ever since he was 3 weeks old. The child was admitted to hospital with symptoms suggesting volvulus or obstruction by a band, and the abdomen was opened. Enterostomy was performed, but death ensued on the following day. The condition proved to be one of congenital stenosis of the ileo-caecal valve, accompanied by colitis and pericolitis, which had given rise to symptoms of partial intestinal obstruction for two years until complete occlusion occurred.

188. Paratyphoid B Phlebitis.

B. GUNNLAUGSSON (*Med. Klinik*, December 13th, 1929, p. 1952) records the case of a woman, aged 69, the subject of varicose veins for years, who was admitted to hospital with a painful swelling on the left thigh, over which the skin was intensely reddened. The dilated saphenous vein was ligatured and a thrombus excised; recovery followed. Culture of the thrombus, as well as of the urine and stools, showed paratyphoid B bacilli. The patient had no signs of enteric fever, so that the discovery of the bacilli was a surprise.

Therapeutics.

189. Treatment of Ringworm of the Scalp.

AFTER commenting on the disadvantages and dangers attending the use of *x* rays and thallium acetate in the treatment of ringworm of the scalp, L. B. KINGERY (*Arch. Derm. and Syph.*, December, 1929, p. 737) records the results of a clinical trial of drugs the fungicidal and fungistatic activities of which have been previously demonstrated *in vitro*. Twelve cases of tinea capitis, eleven of which presented clinically a microsporon infection, and in ten of which the clinical diagnosis was confirmed microscopically, were treated in the following manner. The hair was clipped round the lesions if only one or two were present, and over the entire scalp if the disease was generalized. A washable cap was constantly worn and frequently changed. Soapsud shampoos were given twice a week, and three times daily a solution of gutta-percha in chloroform, containing 0.5 per cent. thymol and 1 per cent. oil of cinnamon, was applied. If this resulted in irritation, the frequency of the applications was decreased. Eight of these cases were cured, both clinically and microscopically, in periods varying from four months to one year; three other patients, according to letters from the parents, have enjoyed complete restoration of hair and no recurrence of symptoms over approximately equivalent periods. In the remaining case the mother reported the necessity of using other remedies, in spite of an apparently favourable response while under observation. Kingery considers that, while the evidence is far too limited to be conclusive, this simple method of treatment might well stand favourable comparison with the older and more complicated ones now in vogue.

190. Treatment of Exophthalmic Goitre.

G. HERRNHEISER and W. REDISCH (*Med. Klinik*, November 22nd, 1929, p. 1814) discuss treatment of exophthalmic goitre by iodine and exposure to *x* rays, and call attention to the mutual interference of these methods. They restrict operative treatment to the acute threatening form of Graves's disease, large multiple adenomata, and cases with tracheal compression. For all other types they recommend trial with *x* rays. They remark that formerly radiation tended to produce capsular thickening, so that if an operation had eventually to be performed the surgical difficulties were increased; modern *x*-ray technique has eliminated this objection. Many authors agree that iodine treatment alone is worth a trial in mild early cases, although others pronounce it dangerous unless used solely prior to operation. Patients who react well to iodine fall into three groups: the first group consists of the very small percentage who are completely cured by iodine treatment continued for six months to a year; patients in the second group are considerably improved by iodine, but must continue the treatment indefinitely; in the third group remission occurs merely in some of the symptoms, or if all are benefited the improvement is only fleeting, in spite of continued iodine medication. Stress is laid on the importance of a preliminary test to determine the patient's suitability for iodine treatment. Schwarz particularly emphasized the mutual incompatibility of iodine and *x*-ray treatment, but the present authors describe cases which contradict this view. Eleven patients in the third group were treated with iodine, and only their nervous and gastro-intestinal symptoms were benefited; after a course of *x* rays the cardiac signs, exophthalmos, subjective symptoms, and the basal metabolic rate were much improved. Fourteen patients were also successfully treated with *x* rays although a preliminary test had revealed unsuitability for iodine administration. Survey of all the results indicated that the course of *x*-ray treatment was quite uninfluenced by previous iodine therapy, and the authors think that occasionally both treatments may be simultaneously employed with good results.

191. Belladonna in Sea-sickness.

J. BOHEC (*Presse Med.*, January 4th, 1930, p. 21) maintains that there are many types of sea-sickness—for example, those of vagotonic, sympathicotonic, amphoneurotonic causation—and that successful treatment, both preventive and curative, depends on a correct diagnosis of the type. Dealing only with the first-named form, he remarks that sea-sickness is usually accompanied by a typical vagotonic crisis, and those individuals predisposed to the malady are usually vagotonics; therefore, as a preventive, a vagus depressant should be given. The well-known beneficial effects of atropine are due to its inhibitory action on the sensory filaments of the pneumogastric and on the motor nerves. Since it also excites the bulbar centre, provoking the nausea reflex and vomiting, it should be combined with a central depressant, such as morphine. Stoll has shown that the active principle of belladonna is not atropine, but the levo-rotatory hyoscyamine. Bohec has for the past year obtained satisfactory results in sea-sickness by the administration of an analogous product, bellafoline, which is composed of the total alkaloids of belladonna in a pure state. Bellafoline is as toxic as atropine, but it is twice as active and its effects last twice as long. The use of morphine has also been abandoned for belladenal, a combination of bellafoline and gardenal. As a preventive, before embarking and during the first days at sea, four tablets of bellafoline (one every two hours) should be given during the day, and, as a necessary complement, two tablets of belladenal on retiring; the latter will ensure a good night's sleep, which in itself is of great curative value. In cases of actual sea-sickness hypodermic injections of bellafoline should be given. It is rarely necessary, the author adds, to give more than 1.5 mg. during twenty-four to thirty-six hours; this should be administered in 0.5 mg. doses at six-hour intervals.

192. The Action of Carbon Dioxide Baths.

F. KOZA (*Bratislavské Lekárske Listy*, November, 1929, p. 1163) describes the action of carbon dioxide baths in eighty cases of arterial hypertension. The temperature of the baths ranged from 27° to 22° C.; the duration of them was twenty minutes. The patients experienced no unusual sensations while in the bath, and the skin did not change colour. Measurement of the carbon dioxide in the expired air proved that much less carbonic acid was absorbed by the skin in a dry carbon dioxide bath than in a wet one; in all cases there was a fall of the blood pressure while the patient was in the bath. The baths had a marked sedative effect on the climacteric disturbances in women, even in the absence of increased blood pressure; they also proved beneficial in cases of angina pectoris with high blood pressure. The author has tested the influence of carbon dioxide on the blood pressure in rabbits with permanent artificially-induced arterial hypertension. In these experiments the carbon dioxide was applied in three different ways: (1) in a gas bath; (2) by means of intraperitoneal insufflation of carbon dioxide; and (3) by means of an infusion of water saturated with carbon dioxide. In each case there followed a fall of the blood pressure amounting to two-thirds of the artificially induced rise. The most rapid and prolonged fall of the blood pressure occurred after the intraperitoneal insufflation of carbon dioxide. Koza believes that carbon dioxide baths act probably through the peripheral vascular system; the stimulation of the respiratory centre by this gas prevents its accumulation in the organism.

193. Harmine (or Banisterin) in Post-encephalitis.

K. BERINGER and K. WILMANNS (*Deut. med. Woch.*, December 13th, 1929, p. 2031) have studied the little-known alkaloids harmine and banisterin, and have confirmed the observations of other workers that these substances are chemically and therapeutically identical, and also with the drug "Yagéin," which was originally obtained from a South American climbing plant known to the natives as "el Yaqué," and was used by them as an intoxicant. The authors have also confirmed by numerous therapeutic investigations on Parkinsonian disease the previously established experience of the action of the drug on the extrapyramidal motor system. The alkaloid causes no injurious effects, and there is no evidence of "habit" resulting from its use. The best results were obtained by subcutaneous injections in doses of 0.02 to 0.04 gram; good results were also obtained by the use of suppositories, and in tablet form by the mouth, though the action is delayed. Harmine is said to be especially indicated in cases of post-encephalitic extrapyramidal disturbances. Sometimes the administration of harmine alone is without effect, but if combined with other alkaloid derivatives of the Solanaceae group good results can be obtained.

Laryngology and Otology.

194. Oesophageal Stricture due to Corrosion.

REBATTU and PARTHIOT (*Rev. de Laryngol., d'Otol. et de Rhinol.*, November 15th, 1929, p. 613) describe the management of cases of injury to the oesophagus following the ingestion of corrosive acids and alkalis. They avoid gastrostomy, if at all possible, giving large quantities of saline solution and glucose by the rectum and copious fluids by the mouth. If, however, there is absolute dysphagia and increasing tachycardia, together with general deterioration of the patient, then only do they perform gastrostomy. They comment on the rapid improvement of the patients following the operation. They state that all these cases result in stricture, which can almost always be treated by dilatation with the aid of the oesophagoscope, there being very few cases where there are indications for the more drastic method of diathermy. The authors advise that at least four weeks should be allowed to elapse before the beginning of treatment by dilatation. Although earlier dilatation is easier and more rapid, the risks to the oesophagus are too great. Dilatation must always be conducted under control of the vision. In very difficult cases the dilatation is started by means of a filiform bougie and then olive-headed gum-elastic bougies are carefully passed. The largest bougie which can be introduced at each sitting is left in the oesophagus till the next day. This is usually well tolerated, but the authors recommend in addition a hypodermic injection of morphine and atropine. Dilatation must be performed at least twice a week until swallowing is normal; since these strictures tend to recur, the passing of a large-sized bougie every three months is advised.

195. Ethmoiditis in Children.

ROUGET and FERRAND (*Arch. Int. de Laryngol.*, September-October, 1929, p. 909) describe cases of ethmoiditis in children which they have had the opportunity of observing in the Hôpital Trousseau. In children ethmoiditis usually occurs without involvement of the other nasal sinuses, in marked contradistinction to the condition in adults. Adenoids constitute an important predisposing cause, and the most severe cases are observed in the acute specific fevers, especially scarlet fever, where there is usually a suppurative condition from the outset of the ethmoidal disease. In studying the bacteriology of these cases it was found that a staphylococcus was present four times as frequently as a streptococcus. Clinically the condition is usually one of an orbital cellulitis with very few signs in the nose. Following a coryza, or in the course of a specific fever, a swelling is noticed at the inner canthus of one eye. There is oedema of both lids, and if the swelling is very marked there may be diplopia, caused by the displacement of the globe outwards and downwards. The maximum pain is felt at the inner aspect of the orbit. The conjunctiva is normal, but there is slight limitation of movement of the globe in a vertical direction in cases associated with much oedema. The fundus is always normal, and signs in the nose are always very slight, but *x*-ray examination shows opacity of the ethmoid on the affected side. In studying the course of these cases two definite types are found—a congestive type, which rapidly subsides, and a suppurative type, where the swelling increases and the temperature remains high. These severe cases usually follow scarlet fever. Prognosis is good in the congestive type, and in the suppurative cases if the ethmoid alone is involved. In streptococcal cases, however, the prognosis must always be guarded, the complications to be feared being orbital phlegmon and meningitis. Treatment of the congestive type is nasal antisepsis, with vaccines in selected cases. Suppurative ethmoiditis must be treated surgically, and the authors regard insomnia as an absolute indication for operation. The orbital route is the approach recommended.

196. Treatment of Mastoiditis in Infants.

F. FIORETTI (*Arch. Ital. di Otol., Rinol. e Laringol.*, November, 1929, p. 703), who records four illustrative cases in children aged from 4 to 12 months, states that, with the exception of a case of fibro-angioma of the parotid, he has never encountered an example of rapid death among all the infants operated on either in the ear, nose, and throat clinic of Rome or in his private practice, whether the operation was performed under a general anaesthetic with ether and chloroform or a local anaesthetic. He is of opinion, however, that in cases of acute mastoiditis in infants it is better to use local in preference to general anaesthesia, and to limit the operation if possible to Wilde's incision and drainage as in the case of an ordinary abscess. He holds that the rapid death described by some authors after otological operations in infants is attributable to the status thymolymphaticus, and particularly to an insufficiency of the chromaffin system.

Obstetrics and Gynaecology.

197. Etiology and Treatment of Membranous Dysmenorrhoea.

G. COTTE (*Presse Méd.*, November 27th, 1929, p. 1542) gives his reasons for disagreement with the generally accepted idea that membranous dysmenorrhoea is the result of an endometritis. In his opinion the pathological findings are not conclusive, and there is not necessarily evidence of inflammation. There are nearly always pains of ovulation at the same time as the menstrual pains. Generally the periods are menorrhagic in type, and, the uterus being found to be voluminous, metritis is at once suspected. Cotte believes that this type of dysmenorrhoea results from some disturbance of the ovarian function which provokes the uterine hyperplasia, the production of membranes and their expulsion being due to functional trouble associated with the uterine mucosa. That the expulsion of membranes is not the sole cause of pain is proved, he thinks, by the results of dilatation and curetting. Further, in these cases, where pregnancy occurs the trouble nearly always returns. Welles records a case of 15-year-old twins who both suffered from this complaint, one so severely that she was compelled to stay in bed for forty-eight hours during each period, which lasted for eight to ten days and was accompanied by much loss of blood, great pain, insomnia, nausea, and vomiting. No therapeutic measures had any success, and ultimately some surgical intervention was considered to be necessary. An abdominal operation was undertaken, and examination revealed the presence of a very large uterus showing no pathological abnormality except hypertrophy. The ovaries and tubes were healthy, and nowhere was there any sign of inflammation, recent or old. The presacral nerve (pelvic sympathetic) was resected for about half an inch and the wound closed. The patient made a normal recovery and returned home. About a year later she reported that she was now quite normal, with regular five to six day periods every twenty-eight days; occasionally small shreds of membrane were passed, but without pain. Vomiting and insomnia had disappeared, and the mental condition had greatly improved. The uterus was found to be less voluminous and to have lost its fibromatous character; micturition had become easy. The membranous dysmenorrhoea of the twin sisters persists and appears to be growing worse, but so far there has been no actual incapacity for work.

198. Puerperal Inversion of the Uterus.

F. S. KELLOGG (*Amer. Journ. Obstet. and Gynecol.*, December, 1929, p. 815) suggests a reclassification of inversion of the uterus subsequent to the birth of the child, and indicates the appropriate treatment for each variety. The first of his three groups comprises cases of acute inversion detected before the formation of the cervical ring; immediate manual replacement from below is the appropriate treatment. The second class includes the more common variety encountered, the inversion being discovered after the formation of the cervical ring. He terms these cases "subacute," and recommends the adoption of Huntington's procedure—namely, abdominal replacement of the inverted uterus. He believes that an attempt to secure replacement by manual pressure from below, or performance of the Spinelli operation, is quite unjustifiable in view of the condition of the tissues. In the third class—that of chronic inversion—the Spinelli type of cervix splitting from below is advised. He adds that, unless inversion occurs in a patient whom he has previously delivered, he prefers to assume that the cervical ring has already formed, and to make use of abdominal replacement, since the ring appears to develop in a very short time.

199. Haematuria in Pregnancy Hydronephrosis.

THOUGH haematuria is well recognized as a symptom of hydronephrosis, and also as occurring during pregnancy, little reference is made in the literature to the fact that in pregnancy the haematuria may be due to a simple hydronephrosis. C. N. SWANSON (*Journ. Amer. Med. Assoc.*, November 16th, 1929, p. 1551) reports the case of a woman, aged 33, who was admitted to hospital with marked haematuria, which persisted during the last four months of pregnancy and the first two weeks of the puerperium; no pathological abnormality other than hydronephrosis could be detected, though several careful urological examinations were made. Labour was uneventful, and there has been no return of the haematuria since the patient's discharge from hospital. The patient's mother suffered similarly in the last of five full-term pregnancies. Swanson remarks that it would seem that serious disease of the genito-urinary tract could be eliminated as a possible explanation of the haematuria, and a blood dyscrasia was equally ruled out by blood tests in this particular patient. He suggests that the blood vessels (capillaries) must have undergone some temporary alteration in consequence of passive congestion, which made them permeable to blood cells over a considerable period of time, while the definite time relationship to gestation indicates that the pregnancy was an actual causal factor. The occurrence of haematuria with hydronephrosis, especially during pregnancy, in both mother and daughter seems to imply that this peculiarity may have been directly transmitted.

Pathology.

200. The Blood Diastase after Operations on the Stomach.

SINCE various workers have shown that traumatic injury of the pancreas, or its experimental production in dogs, leads to an increase in the diastase in the blood, and some injury to the pancreas is inevitable in the surgical treatment of a proportion of gastric and duodenal ulcers, particularly when they are of the penetrating type, H. L. POPPER (*Deut. Zeit. f. Chir.*, November, 1929, p. 273) has estimated the diastase content of the blood in 50 cases of gastrectomy (17 gastric ulcers, 25 duodenal ulcers, 6 carcinomas, and 2 extensive adhesions). The tests were carried out on citrated blood before the operation, six to eight hours after it, and again twenty-four hours after it; they were repeated subsequently if there was any rise. In 41 cases no change was revealed or only a minimal post-operative rise; in 4 there was a slight rise of short duration, and in 5 a definite rise. Of the last five patients two died, and the post-mortem examination revealed peritonitis and fat-necrosis. Popper advocates that the diastase content of the blood should be watched in those patients in whom the pancreas may have been injured at the gastric operation, as well as in those in whom post-operative tachycardia, meteorism, or other peritoneal symptoms suggest incipient pancreatitis. If the diastase value, estimated daily or twice a day, shows a persistently high value, or continues to rise, it may be taken in conjunction with other clinical signs as evidence of involvement of the pancreas, and as an indication for early laparotomy before a failing heart and general toxaemia make the prognosis practically hopeless.

201. Sterilization of Insulin.

U. CAZZANI (*Biochem. e Terap. Sperim.*, November 30th, 1929, p. 563) has noted the changes in the hypoglycaemic effect of insulin after sterilization by heat for varying periods, by filtration, and by exposure to ultra-violet radiation. Rabbits kept without food for twenty-four hours were injected subcutaneously with 0.3 c.cm. of insulin solution, containing 10 clinical units per cubic centimetre, the *p*H being 4; the blood sugar was estimated by Bertrand's method, using 4 c.cm. of blood obtained either at the hypoglycaemic crisis or three hours after the injection of the insulin. Cazzani finds that a solution of insulin, of reaction about *p*H 4, can be heated to boiling point for five minutes with only slight loss of hypoglycaemic action, that this loss is increased by prolonged heating, and that after heating for thirty minutes, with complete sterilization, the hypoglycaemic crisis is reduced from 100 per cent. to 33 per cent.; the same insulin solution filtered through Berkefeld candle V, or exposed to ultra-violet radiation for half an hour before being injected into rabbits, failed in every instance to produce the typical convulsions of hypoglycaemia. The author explains the varying effects of heat, filtration, and radiation of insulin solutions reported in the literature as due to the varying methods of preparing the solution.

202. Experimental Tuberculosis Infection by the Nose.

P. REMLINGER and J. BAILLY (*C. R. Soc. de Biologie*, December 13th, 1929, p. 821) have compared the conjunctival and the nasal routes of inoculation of tubercle bacilli into guinea-pigs. In the first experiment two suspensions, one of human and one of bovine bacilli, each containing 10 mg. of bacilli per cubic centimetre, were prepared; one drop, containing 0.5 mg. of bacilli, was allowed to fall into the eye or the nose of a small series of guinea-pigs. Two animals inoculated intranasally with the human strain died after an average time of 91.5 days, whereas the two inoculated through the eye died after 103 days. The two animals inoculated intranasally with the bovine strain died in 109 days, and the two by the eye in 88.5 days. The experiment was repeated on the same number of animals, and the figures obtained were 152.5, 157.5, 71.5, and 118 days respectively. These experiments suggest that death after intranasal inoculation occurs perhaps even more rapidly than after conjunctival inoculation. The general course of the illness and the post-mortem lesions were approximately the same whatever the route used for inoculation. The authors explain their results by supposing that the foreign material introduced into the nose remains longer in contact with the mucosa than when introduced into the conjunctival sac.

FELAMINE

BRAND

SANDOZ

Felamine, an association of the most powerful cholagogue—pure crystallised cholic acid—and the classical biliary disinfectant—hexamine, provides a rational and effective treatment of biliary lithiasis, cholangitis, hepatitis, icterus, and all the symptoms of biliary insufficiency.

Felamine contains no accessory drugs. The cholagogic active principle (cholic acid) is present in an absolutely pure state, free from useless and harmful bile substances.

Indications.

Cholangitis, Cholecystitis, Hepatic Insufficiency, Hepatic Congestion, Jaundice, Chronic Constipation.

Felamine is supplied in Bottles of 50 and 250 Tablets at 5/- *and* 20/-

THE CURTIS ABDOMINAL SUPPORT

(MODEL No 1)

FOR EFFICIENCY

Based on the principle of a direct anterior-posterior pressure, the Curtis Abdominal Support enjoys considerable advantage over any other support on the market.

It gives direct abdominal uplift without any cramping or binding of the hips whatsoever, which is maintained in any position that the patient may assume. May be adjusted to any degree the physician may prescribe, and is simply fastened by a strap and buckle.

For full particulars apply to:

A Remarkable advance in the presentation of H_2O_2

Also in exactly similar form and price—
SOLID IODINE

Owing to the rapidity in which H_2O_2 ordinarily loses its strength, it has not usually been practicable to carry a supply about without risk of frequent replacement; also, of course, of breakage.
Now a new process has been introduced of presenting Peroxide of Hydrogen in a solidified form, so as to enable it to be included conveniently in the physician's or surgeon's everyday case of instruments, etc.

This Solidified Peroxide of Hydrogen is known under the trade name of 'Peroxtik.' It is guaranteed to maintain its original 10-volume strength for a reasonable period.
A full-size tube of this new product will gladly be sent to the Medical Profession FREE on application to the Medical Dept., Messrs. Arthur H. Cox & Co., Ltd., 93, Lewes Road, Brighton, or can be purchased from the usual sources, at the cost of 1/3.

'Peroxtik'
SOLIDIFIED PEROXIDE OF HYDROGEN
in neat, handy glass tubes.

PEPTONE "STERULES" in ASTHMA (REGISTERED TRADE MARK)

Also employed with success in hay fever, associated skin affections, angio-neurotic œdema, cyclic vomiting, periodic diarrhœa, and the migraine-epilepsy syndrome; in short, to such conditions as exhibit an anaphylactic character or sensitisation.

Graded Series of 10 Sterules, 7/6. Continuation Course of 6 Sterules—per box, 6/6—for intravenous and intramuscular use; please state which is desired.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacterioiogical, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one or the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.
